Links: Repository | Issues | Releases | Community

sasoptpy is a Python package that provides a modeling interface for SAS Viya and SAS/OR optimization solvers. It provides a quick way for users to deploy optimization models and solve them by using the SAS Viya Optimization Action Set.

sasoptpy can handle linear, mixed integer linear, nonlinear, and black-box optimization problems. You can use native Python structures like dictionaries, tuples, and lists to define an optimization problem. *sasoptpy* supports Pandas objects extensively.

Under the hood, *sasoptpy* uses the swat package to communicate with SAS Viya, and uses the saspy package to communicate with SAS 9.4 installations.

sasoptpy is an interface to SAS Optimization solvers. Check SAS/OR and PROC OPTMODEL for more details about optimization tools provided by SAS and an interface to model optimization problems inside SAS.

See the SAS Global Forum paper: Optimization Modeling with Python and SAS Viya

CHAPTER

ONE

OVERVIEW

1.1 About sasoptpy

sasoptpy is a Python package that provides easy and integrated ways of working with SAS Optimization and SAS/OR optimization solvers. It enables developers to model optimization problems with ease by providing high-level building blocks.

1.1.1 Capabilities

sasoptpy is very flexible in terms of optimization problem types it supports and workflow alternatives.

Solvers

It currently supports the following model types:

- Linear problems
- Integer linear problems / Mixed integer linear problems
- Quadratic problems
- Nonlinear / Black-box problems

Data

It supports working with both client-side data and server-side data. When data are available on the client-side, it populates the model with integrated data and brings the solution back to the client. When data are available on the server-side, it generates the code to be able to populate the model on the server. You can retrieve the final solution after the solve.

Platforms

sasoptpy can be used with SAS Viya 3.3 or later and SAS 9.4, in all the supporting operating systems.

1.1.2 Road map

sasoptpy has the broader goal of supporting all the functionality of the SAS Optimization and SAS/OR solvers, and providing a high-level set of tools for easily working with models.

1.1.3 Versioning

sasoptpy follows Semantic Versioning as of version 1.0.0.

- Any backwards incompatible changes increase the major version number (X.y.z).
- Minor changes and improvements increase the the minor version number (x.Y.z).
- Patches increase the patch version number (x.y.Z).
- Pre-releases are marked by using *alpha* and *beta*, and release candidates are marked using *rc* identifiers.

1.1.4 License

sasoptpy is an open-source package and uses the standard *Apache 2.0 license*.

1.1.5 Support

Have any questions?

- If you have a package-related issue, feel free to report it on GitHub.
- If you have an optimization-related question, consider asking it on SAS Communities.
- For further technical support, reach SAS Technical Support.

1.1.6 Contribution

Contributions are always welcome. Clone the project to your working environment and submit pull requests as you see fit. For more details, see the guidelines at the GitHub repository.

1.1.7 Highlighted Works

A list of highlighted projects and blog posts:

- Fastest, cheapest, greenest: How will football fans choose which matches to attend?
- 1 tournament, 12 countries: A logistical maze?
- Using SAS Optimization with Python and containers
- Bringing Analytics to the Soccer Transfer Season
- Visiting all 30 Major League Baseball Stadiums - with Python and SAS Viya

1.2 What's New

1.2.1 v1.0.0-alpha (TBD)

New Features

- Added workspaces; see more info in *User Guide* and *example*
- Added *configurations*
- Added *abstract actions* that allow server-side operations. Highlights include:
  - `actions.read_data()` and `actions.create_data()`
  - `actions.for_loop()` and `actions.cofor_loop()`
  - `actions.print_item()`
  - `actions.solve()`
- Added structure decorators for better control of submissions

Changes

- Refactored the entire package. sasoptpy now has *core*, *abstract*, *interface*, *session*, and *util* directories
- Experimental RESTful API was dropped
- *get_obj_by_name* function was removed
- *lso* solver was renamed to *blackbox*
- Because of the use of literal strings (**PEP 498**), only Python 3.6 or later versions are supported

Bug Fixes

- Fixed: Arithmetic operations with powers are generating incorrect results
- Fixed: Variable groups with space in their index are not getting values
- Fixed: Constraints without directions do not produce an error
- Fixed: Documentation does not mention conda-forge library requirement
- Fixed: Single-dimensional parameters are hard to access

1.3 License

(continues on next page)

(continued from previous page)

```
      and distribution as defined by Sections 1 through 9 of this document.

      "Licensor" shall mean the copyright owner or entity authorized by
      the copyright owner that is granting the License.

      "Legal Entity" shall mean the union of the acting entity and all
      other entities that control, are controlled by, or are under common
      control with that entity. For the purposes of this definition,
      "control" means (i) the power, direct or indirect, to cause the
      direction or management of such entity, whether by contract or
      otherwise, or (ii) ownership of fifty percent (50%) or more of the
      outstanding shares, or (iii) beneficial ownership of such entity.

      "You" (or "Your") shall mean an individual or Legal Entity
      exercising permissions granted by this License.

      "Source" form shall mean the preferred form for making modifications,
      including but not limited to software source code, documentation
      source, and configuration files.

      "Object" form shall mean any form resulting from mechanical
      transformation or translation of a Source form, including but
      not limited to compiled object code, generated documentation,
      and conversions to other media types.

      "Work" shall mean the work of authorship, whether in Source or
      Object form, made available under the License, as indicated by a
      copyright notice that is included in or attached to the work
      (an example is provided in the Appendix below).

      "Derivative Works" shall mean any work, whether in Source or Object
      form, that is based on (or derived from) the Work and for which the
      editorial revisions, annotations, elaborations, or other modifications
      represent, as a whole, an original work of authorship. For the purposes
      of this License, Derivative Works shall not include works that remain
      separable from, or merely link (or bind by name) to the interfaces of,
      the Work and Derivative Works thereof.

      "Contribution" shall mean any work of authorship, including
      the original version of the Work and any modifications or additions
      to that Work or Derivative Works thereof, that is intentionally
      submitted to Licensor for inclusion in the Work by the copyright owner
      or by an individual or Legal Entity authorized to submit on behalf of
      the copyright owner. For the purposes of this definition, "submitted"
      means any form of electronic, verbal, or written communication sent
      to the Licensor or its representatives, including but not limited to
      communication on electronic mailing lists, source code control systems,
      and issue tracking systems that are managed by, or on behalf of, the
      Licensor for the purpose of discussing and improving the Work, but
      excluding communication that is conspicuously marked or otherwise
      designated in writing by the copyright owner as "Not a Contribution."

      "Contributor" shall mean Licensor and any individual or Legal Entity
      on behalf of whom a Contribution has been received by Licensor and
      subsequently incorporated within the Work.

   2. Grant of Copyright License. Subject to the terms and conditions of
```

(continues on next page)

(continued from previous page)

```
   this License, each Contributor hereby grants to You a perpetual,
   worldwide, non-exclusive, no-charge, royalty-free, irrevocable
   copyright license to reproduce, prepare Derivative Works of,
   publicly display, publicly perform, sublicense, and distribute the
   Work and such Derivative Works in Source or Object form.

3. Grant of Patent License. Subject to the terms and conditions of
   this License, each Contributor hereby grants to You a perpetual,
   worldwide, non-exclusive, no-charge, royalty-free, irrevocable
   (except as stated in this section) patent license to make, have made,
   use, offer to sell, sell, import, and otherwise transfer the Work,
   where such license applies only to those patent claims licensable
   by such Contributor that are necessarily infringed by their
   Contribution(s) alone or by combination of their Contribution(s)
   with the Work to which such Contribution(s) was submitted. If You
   institute patent litigation against any entity (including a
   cross-claim or counterclaim in a lawsuit) alleging that the Work
   or a Contribution incorporated within the Work constitutes direct
   or contributory patent infringement, then any patent licenses
   granted to You under this License for that Work shall terminate
   as of the date such litigation is filed.

4. Redistribution. You may reproduce and distribute copies of the
   Work or Derivative Works thereof in any medium, with or without
   modifications, and in Source or Object form, provided that You
   meet the following conditions:

   (a) You must give any other recipients of the Work or
       Derivative Works a copy of this License; and

   (b) You must cause any modified files to carry prominent notices
       stating that You changed the files; and

   (c) You must retain, in the Source form of any Derivative Works
       that You distribute, all copyright, patent, trademark, and
       attribution notices from the Source form of the Work,
       excluding those notices that do not pertain to any part of
       the Derivative Works; and

   (d) If the Work includes a "NOTICE" text file as part of its
       distribution, then any Derivative Works that You distribute must
       include a readable copy of the attribution notices contained
       within such NOTICE file, excluding those notices that do not
       pertain to any part of the Derivative Works, in at least one
       of the following places: within a NOTICE text file distributed
       as part of the Derivative Works; within the Source form or
       documentation, if provided along with the Derivative Works; or,
       within a display generated by the Derivative Works, if and
       wherever such third-party notices normally appear. The contents
       of the NOTICE file are for informational purposes only and
       do not modify the License. You may add Your own attribution
       notices within Derivative Works that You distribute, alongside
       or as an addendum to the NOTICE text from the Work, provided
       that such additional attribution notices cannot be construed
       as modifying the License.

   You may add Your own copyright statement to Your modifications and
```

(continues on next page)

(continued from previous page)

```
      may provide additional or different license terms and conditions
      for use, reproduction, or distribution of Your modifications, or
      for any such Derivative Works as a whole, provided Your use,
      reproduction, and distribution of the Work otherwise complies with
      the conditions stated in this License.

   5. Submission of Contributions. Unless You explicitly state otherwise,
      any Contribution intentionally submitted for inclusion in the Work
      by You to the Licensor shall be under the terms and conditions of
      this License, without any additional terms or conditions.
      Notwithstanding the above, nothing herein shall supersede or modify
      the terms of any separate license agreement you may have executed
      with Licensor regarding such Contributions.

   6. Trademarks. This License does not grant permission to use the trade
      names, trademarks, service marks, or product names of the Licensor,
      except as required for reasonable and customary use in describing the
      origin of the Work and reproducing the content of the NOTICE file.

   7. Disclaimer of Warranty. Unless required by applicable law or
      agreed to in writing, Licensor provides the Work (and each
      Contributor provides its Contributions) on an "AS IS" BASIS,
      WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or
      implied, including, without limitation, any warranties or conditions
      of TITLE, NON-INFRINGEMENT, MERCHANTABILITY, or FITNESS FOR A
      PARTICULAR PURPOSE. You are solely responsible for determining the
      appropriateness of using or redistributing the Work and assume any
      risks associated with Your exercise of permissions under this License.

   8. Limitation of Liability. In no event and under no legal theory,
      whether in tort (including negligence), contract, or otherwise,
      unless required by applicable law (such as deliberate and grossly
      negligent acts) or agreed to in writing, shall any Contributor be
      liable to You for damages, including any direct, indirect, special,
      incidental, or consequential damages of any character arising as a
      result of this License or out of the use or inability to use the
      Work (including but not limited to damages for loss of goodwill,
      work stoppage, computer failure or malfunction, or any and all
      other commercial damages or losses), even if such Contributor
      has been advised of the possibility of such damages.

   9. Accepting Warranty or Additional Liability. While redistributing
      the Work or Derivative Works thereof, You may choose to offer,
      and charge a fee for, acceptance of support, warranty, indemnity,
      or other liability obligations and/or rights consistent with this
      License. However, in accepting such obligations, You may act only
      on Your own behalf and on Your sole responsibility, not on behalf
      of any other Contributor, and only if You agree to indemnify,
      defend, and hold each Contributor harmless for any liability
      incurred by, or claims asserted against, such Contributor by reason
      of your accepting any such warranty or additional liability.

   END OF TERMS AND CONDITIONS
```

CHAPTER

TWO

INSTALLATION

2.1 Python version support and dependencies

sasoptpy is developed and tested for Python version 3.6+.

It requires the following packages:

- numpy
- saspy
- swat
- pandas

2.2 Getting sasoptpy

You can install *sasoptpy* by using *pip* or *conda*:

```
pip install sasoptpy

conda install -c sas-institute sasoptpy
```

Any dependencies should be installed automatically.

Depending on your installation, you might need to add *conda-forge* channel to *conda* by using:

```
conda config --append channels conda-forge
```

2.2.1 GitHub repository

You can also get stable and development versions of *sasoptpy* from the GitHub repository. To get the latest version, call:

```
git clone https://github.com/sassoftware/sasoptpy.git
```

Then inside the sasoptpy folder, call:

```
pip install .
```

Alternatively, you can use:

```
python setup.py install
```

CHAPTER

THREE

USER GUIDE

3.1 Introduction to Optimization

Optimization is an umbrella term for maximizing or minimizing a given target, which can be represented as a function. It is often used in real-life problems from finance to aviation, from chemistry to sports analytics.

Optimization problems can describe a business problem or a physical concept. Any phenomena that can be represented as a function can be optimized by several algorithms. It lies at the heart of several tools we use every day, from routing to Machine Learning.

3.1.1 Steps of Optimization

Optimization problems often consists of the following steps[1,2]:

1. Observe the system and define the problem
2. Gather relevant data
3. Develop a formulation
4. Solve the model
5. Interpret the solution

Often, a process is observed by the modeler to identify the problems. Several examples are finding the shortest path between two locations, maximizing a profit, and maximizing the accuracy of a handwriting recognition algorithm.

Collecting data is often the most daunting process. In the age of big data, it is often difficult to distinguish noise from relevant data. After data are gathered, you can write a formulation. A proper formulation is critical because features such as linearity and convexity greatly impact the performance of solution algorithms, especially for large problems.

Solving a model requires an optimization algorithm. SAS Optimization provides several optimization algorithms to solve a variety of different formulations. See *types of optimization* for more information on this topic.

Finally, the modeler should decide whether the result of an optimization process is valid. If not, the process should be repeated by adding the missing pieces until a satisfactory result is obtained.

[1] Hillier, Frederick S., and Gerald J. Lieberman. Introduction to operations research. McGraw-Hill Science, Engineering & Mathematics, 1995.
[2] SAS Institute. SAS/OR 15.1 User's Guide: Mathematical Programming Examples. SAS institute, 2018.

3.1.2 Basic Elements

There might be several elements in the definition of an optimization formulation. To clarify these elements, consider an optimization problem of finding a route from your home to the airport.

1. **Variables**: Variables are parameters that the optimization algorithm tunes. In the example, the decisions of which roads to be used are decision variables. An optimization algorithm determines optimal values for variables in the problem.
2. **Objective**: An objective is the measure of performance that is to be maximized or minimized. An objective is a function of variables in a problem, meaning an objective value is obtained for given values of variables in an optimization problem. In the example, the objective function is the time to reach the airport. The optimization algorithm should decide which roads to use in order to minimize the travel time.
3. **Constraints**: Constraints are restrictions on variables that prevent illogical solutions. In the example, the amount of fuel in the car places a restriction on how far you can drive. You can the force optimization algorithm to find a solution under a certain mileage, even if there are other solutions which could be shorter in terms of travel time.

In short, *optimization* is choosing **variable** values to maximize or minimize an **objective** function subject to certain **constraints**.

3.1.3 Simple Problem

Let us consider a simple example. The following problem (Brewer's Dilemma) is a simplified Resource Allocation problem, presented by Robert G. Bland[3].

In the problem, a brewer has limited corn, hops, and barley malt inventory. The brewer wants to produce Ale and Beer that will maximize the total profit. Each product requires a certain amount of these three ingredients, as follows:

(per barrel)	Amount Required			
Product	Corn	Hops	Barley Malt	Profit
Ale	5 pounds	4 ounces	35 pounds	$13
Beer	15 pounds	4 ounces	20 pounds	$23
(Total Available)	480 pounds	160 ounces	1,190 pounds	

The **variables** in this problem are to decide how many barrels of ale and beer to produce. Let us call them *ale* and *beer*. It might be intuitive to prefer beer to ale due to its higher profit rate. However, doing so might deplete all the resources faster and might leave you with excess amount of hops and barley malt.

The **objective** in this problem is to maximize the total profit function, which is $13 \cdot \text{ale} + 23 \cdot \text{beer}$.

Each limitation on ingredients is a **constraint**. For corn, hops, and barley malt, the following constrains apply:

$$5 \cdot \text{ale} + 15 \cdot \text{beer} \leq 480$$
$$4 \cdot \text{ale} + 4 \cdot \text{beer} \leq 160$$
$$35 \cdot \text{ale} + 20 \cdot \text{beer} \leq 1,190$$

Combining all items, the optimization formulation is written as follows:

$$\begin{array}{llll}
\text{maximize:} & 13 \cdot \text{ale} & +23 \cdot \text{beer} & \\
\text{subject to:} & & & \\
& 5 \cdot \text{ale} & + 15 \cdot \text{beer} & \leq & 480 \\
& 4 \cdot \text{ale} & + 4 \cdot \text{beer} & \leq & 160 \\
& 35 \cdot \text{ale} & + 20 \cdot \text{beer} & \leq & 1,190 \\
& & \text{ale} & \geq & 0 \\
& & \text{beer} & \geq & 0
\end{array}$$

[3] Bland, Robert G. "The Allocation of Resources by Linear Programming." Scientific American 244 (1981): 126-144.

This problem is small enough to be solved by hand, but let us consider some alternatives.

	Barrels produced		
#	Ale	Beer	Profit
1	34	0	$442
2	0	32	$736
3	15	25	$770
4	12	28	$800

Producing only ale or beer is inferior to producing a combination of the two, for obvious reasons. Finding the exact ratio that will maximize the profit might be tricky, as seen in solutions 3 and 4. Indeed, solution 4 gives the optimal values that maximize the profit in this example.

Some additional examples of problems that can be formulated as optimization problems are as follows:

- Scheduling project steps to minimize total completion, where tasks might depend on completion of earlier tasks
- Choosing distribution centers for retailers to minimize total cost while satisfying customer demands on time
- Assigning soccer players to a squad to maximize the total rating of the team under foreign player rules
- Finding the cheapest travel option and shortest route between two cities
- Blending chemical products to minimize the total cost while achieving a certain efficiency of detergents
- Choosing a price that will maximize the total profit in a competitive market

See the related section of SAS Optimization 8.5 Mathematical Optimization Procedures[4] for more information about optimization problems and examples.

3.1.4 Types of Optimization

The structure of a formulation affects which algorithms can be deployed to solve a problem. The most common optimization types are as follows:

- **Linear optimization**: If the objective function and all constraints of a problem can be described by linear mathematical relations, and if all decision variables are continuous, the formulation is called a Linear problem (LP). LPs are one of the easiest problems in terms of solution time and well-studied in literature.
- **Mixed integer linear optimization**: If a linear formulation involves binary (on/off type decisions) or integer variables, that problem is an Integer Linear Problem (ILP) or Mixed Integer Linear Problem (MILP) depending on variables. MILPs are very popular as many real-life problems can be represented as MILPs.
- **Nonlinear optimization**: If a problem involves nonlinear objectives or constraints (such as exponential, polynomial, absolute values) the problem is called a nonlinear problem (NLP).

[4] https://go.documentation.sas.com/?cdcId=pgmsascdc&cdcVersion=9.4_3.5&docsetId=casmopt&docsetTarget=casmopt_intro_toc.htm&locale=en

3.2 Basic Functionality

Solving an optimization problem via *sasoptpy* starts with having a running CAS (SAS Viya) Server or having a SAS 9.4 installation. It is possible to model a problem without a connection but solving a problem requires access to SAS Optimization or SAS/OR solvers at runtime.

3.2.1 Creating a session

Creating a SAS Viya session

sasoptpy uses the CAS connection provided by the swat package. After installation simply use:

```
In [1]: from swat import CAS

In [2]: s = CAS(hostname, port, userid, password)
```

The last two parameters are optional for some use cases. See swat Documentation for more details.

Creating a SAS 9.4 session

To create a SAS 9.4 session, see saspy Documentation. After customizing the configurations for your setup, you can create a session as follows:

```
import saspy
s = saspy.SASsession(cfgname='winlocal')
```

3.2.2 Initializing a model

After creating an active CAS or SAS session, you can create an empty model as follows:

```
In [3]: import sasoptpy as so

In [4]: m = so.Model(name='my_first_model', session=s)
NOTE: Initialized model my_first_model.
```

This command creates an empty model.

3.2.3 Processing input data

The easiest way to work with *sasoptpy* is to define problem inputs as Pandas DataFrames. You can define objective and cost coefficients, and lower and upper bounds by using the DataFrame and Series objects. See Pandas Documentation to learn more.

```
In [5]: import pandas as pd

In [6]: prob_data = pd.DataFrame([
   ...:     ['Period1', 30, 5],
   ...:     ['Period2', 15, 5],
   ...:     ['Period3', 25, 0]
   ...:     ], columns=['period', 'demand', 'min_prod']).set_index(['period'])
   ...:
```

(continues on next page)

(continued from previous page)

```
In [7]: price_per_product = 10

In [8]: capacity_cost = 10
```

You can extract the set `PERIODS` and the other fields `demand` and `min_production` as follows:

```
In [9]: PERIODS = prob_data.index.tolist()

In [10]: demand = prob_data['demand']

In [11]: min_production = prob_data['min_prod']
```

3.2.4 Adding variables

You can add a single variable or a set of variables to *Model* objects.

- *Model.add_variable()* method is used to add a single variable.

  ```
  In [12]: production_cap = m.add_variable(vartype=so.INT, name='production_cap',␣
  ↪lb=0)
  ```

  When working with multiple models, you can create a variable independent of the model, such as

  ```
  >>> production_cap = so.Variable(name='production_cap', vartype=so.INT, lb=0)
  ```

  and add it to an existing model by using

  ```
  >>> m.include(production_cap)
  ```

- The *Model.add_variables()* method is used to add a set of variables.

  ```
  In [13]: production = m.add_variables(PERIODS, vartype=so.INT, name='production',
     ....:                              lb=min_production)
     ....:
  ```

  When passed as a set of variables, you can retrieve individual variables by using individual keys, such as `production['Period1']`. To create multidimensional variables, simply list all the keys as follows:

  ```
  >>> multivar = m.add_variables(KEYS1, KEYS2, KEYS3, name='multivar')
  ```

3.2.5 Creating expressions

Expression objects hold mathematical expressions. Although these objects are mostly used under the hood when defining a model, it is possible to define a custom *Expression* to use later.

```
In [14]: totalRevenue = production.sum('*')*price_per_product

In [15]: totalCost = production_cap * capacity_cost
```

Note the use of the *VariableGroup.sum()* method over a variable group. This method returns the sum of variables inside the group as an *Expression* object. Its multiplication with a scalar `price_per_product` gives the final expression.

Similarly, `totalCost` is simply multiplication of a *Variable* object with a scalar.

3.2.6 Setting an objective function

You can define objective functions in terms of expressions. In this problem, the objective is to maximize the profit, so the *Model.set_objective()* method is used as follows:

```
In [16]: m.set_objective(totalRevenue-totalCost, sense=so.MAX, name='totalProfit')
Out[16]: sasoptpy.Expression(exp = 10 * production[Period1] + 10 *␣
↪production[Period2] + 10 * production[Period3] - 10 * production_cap, name=
↪'totalProfit')
```

Notice that you can define the same objective by using:

```
>>> m.set_objective(production.sum('*')*price_per_product - production_cap*capacity_
↪cost, sense=so.MAX, name='totalProfit')
```

The mandatory argument `sense` should be assigned the value of either `so.MIN` or `so.MAX` for minimization or maximization problems, respectively.

3.2.7 Adding constraints

In *sasoptpy*, constraints are simply expressions with a direction. It is possible to define an expression and add it to a model by defining which direction the linear relation should have.

There are two methods to add constraints. The first one is *Model.add_constraint()* where a single constraint can be added to a model.

The second one is *Model.add_constraints()* where multiple constraints can be added to a model.

```
In [17]: m.add_constraints((production[i] <= production_cap for i in PERIODS),
   ....:                   name='capacity')
   ....:
Out[17]: sasoptpy.ConstraintGroup([production[Period1] - production_cap <=  0,␣
↪production[Period2] - production_cap <=  0, production[Period3] - production_cap <=␣
↪ 0], name='capacity')
```

```
In [18]: m.add_constraints((production[i] <= demand[i] for i in PERIODS),
   ....:                   name='demand')
   ....:
Out[18]: sasoptpy.ConstraintGroup([production[Period1] <=  30, production[Period2] <=␣
↪ 15, production[Period3] <=  25], name='demand')
```

Here, the first term provides a Python generator, which then gets translated into constraints in the problem. The symbols <=, >=, and == are used for less than or equal to, greater than or equal to, and equal to constraints, respectively. You can define range constraints by using == symbol and a list of two values that represent lower and upper bounds.

```
In [19]: m.add_constraint(production['Period1'] == [10, 100], name='production_bounds
↪')
Out[19]: sasoptpy.Constraint(production[Period1] ==  [10, 100], name='production_
↪bounds')
```

3.2.8 Solving a problem

After a problem is defined, you can send it to the CAS server or SAS session by calling the `Model.solve()` method. The `Model.solve()` method returns the primal solution when available, and `None` otherwise.

```
In [20]: m.solve()
NOTE: Added action set 'optimization'.
NOTE: Converting model my_first_model to OPTMODEL.
NOTE: Submitting OPTMODEL code to CAS server.
NOTE: Problem generation will use 8 threads.
NOTE: The problem has 4 variables (0 free, 0 fixed).
NOTE: The problem has 0 binary and 4 integer variables.
NOTE: The problem has 7 linear constraints (6 LE, 0 EQ, 0 GE, 1 range).
NOTE: The problem has 10 linear constraint coefficients.
NOTE: The problem has 0 nonlinear constraints (0 LE, 0 EQ, 0 GE, 0 range).
NOTE: The OPTMODEL presolver is disabled for linear problems.
NOTE: The initial MILP heuristics are applied.
NOTE: The MILP presolver value AUTOMATIC is applied.
NOTE: The MILP presolver removed all variables and constraints.
NOTE: Optimal.
NOTE: Objective = 400.
NOTE: The output table 'SOLUTION' in caslib 'CASUSER(casuser)' has 4 rows and 6␣
↪columns.
NOTE: The output table 'DUAL' in caslib 'CASUSER(casuser)' has 7 rows and 4 columns.
NOTE: The CAS table 'solutionSummary' in caslib 'CASUSER(casuser)' has 18 rows and 4␣
↪columns.
NOTE: The CAS table 'problemSummary' in caslib 'CASUSER(casuser)' has 20 rows and 4␣
↪columns.
Out[20]:
Selected Rows from Table SOLUTION

     i                  var  value   lb            ub   rc
0  1.0       production_cap   25.0 -0.0  1.797693e+308 NaN
1  2.0  production[Period1]   25.0  5.0  1.797693e+308 NaN
2  3.0  production[Period2]   15.0  5.0  1.797693e+308 NaN
3  4.0  production[Period3]   25.0 -0.0  1.797693e+308 NaN
```

At the end of the solve operation, the solver returns both Problem Summary and Solution Summary tables. These tables can later be accessed by using `m.get_problem_summary()` and `m.get_solution_summary()`.

```
In [21]: print(m.get_solution_summary())
Selected Rows from Table SOLUTIONSUMMARY

                                Value
Label
Solver                           MILP
Algorithm              Branch and Cut
Objective Function        totalProfit
Solution Status               Optimal
Objective Value                   400

Relative Gap                        0
Absolute Gap                        0
Primal Infeasibility                0
Bound Infeasibility                 0
Integer Infeasibility               0

Best Bound                        400
```

(continues on next page)

(continued from previous page)

```
Nodes                               0
Solutions Found                     3
Iterations                          0
Presolve Time                    0.01
Solution Time                    0.02
```

3.2.9 Printing solutions

You can retrieve the solutions by using the *sasoptpy.get_solution_table()* method. It is strongly suggested to group variables and expressions that share the same keys in a call.

```
In [22]: print(so.get_solution_table(demand, production))
        demand  production
period
Period1     30        25.0
Period2     15        15.0
Period3     25        25.0
```

As seen, a Pandas Series and a Variable object that have the same index keys are printed in this example.

3.2.10 Initializing a workspace

If you would like to use extensive abstract modeling capabilities of *sasoptpy*, you can create a workspace. Workspaces support features like server-side for loops, cofor loops (parallel), read data, and create data. You can initialize a *sasoptpy.Workspace* by using Python's *with* keyword. As an example, you can create a workspace with a set and a variable group as follows:

```
In [23]: def create_workspace():
   ....:     with so.Workspace(name='my_workspace', session=s) as w:
   ....:         I = so.Set(name='I', value=range(1, 11))
   ....:         x = so.VariableGroup(I, name='x', lb=0)
   ....:     return w
   ....:
```

```
In [24]: workspace = create_workspace()

In [25]: print(so.to_optmodel(workspace))
proc optmodel;
   set I = 1..10;
   var x {{I}} >= 0;
quit;
```

You can submit a workspace to a CAS server and retrieve the response by using:

```
In [26]: workspace.submit()
NOTE: Added action set 'optimization'.
NOTE: The output table 'SOLUTION' in caslib 'CASUSER(casuser)' has 10 rows and 6␣
↪columns.
NOTE: The output table 'DUAL' in caslib 'CASUSER(casuser)' has 0 rows and 4 columns.
Out[26]:
Selected Rows from Table SOLUTION

      i    var  value   lb              ub  rc
```

(continues on next page)

(continued from previous page)

```
0   1.0   x[1]    0.0  0.0  1.797693e+308 NaN
1   2.0   x[2]    0.0  0.0  1.797693e+308 NaN
2   3.0   x[3]    0.0  0.0  1.797693e+308 NaN
3   4.0   x[4]    0.0  0.0  1.797693e+308 NaN
4   5.0   x[5]    0.0  0.0  1.797693e+308 NaN
5   6.0   x[6]    0.0  0.0  1.797693e+308 NaN
6   7.0   x[7]    0.0  0.0  1.797693e+308 NaN
7   8.0   x[8]    0.0  0.0  1.797693e+308 NaN
8   9.0   x[9]    0.0  0.0  1.797693e+308 NaN
9  10.0  x[10]    0.0  0.0  1.797693e+308 NaN
```

3.2.11 Package configurations

You can change the default options regarding problem representation as follows:

```
In [27]: x = so.Variable(name='x')

In [28]: c = so.Constraint(10 / 3 * x + 1e-20 * x ** 2 <= 30 + 1e-11, name='c')

In [29]: print(so.to_definition(c))
con c : 3.333333333333 * x + 0.0 * ((x) ^ (2)) <= 30.00000000001;
```

```
In [30]: so.config['max_digits'] = 2
```

```
In [31]: print(so.to_definition(c))
con c : 3.33 * x + 0.0 * ((x) ^ (2)) <= 30.0;
```

```
In [32]: so.config['max_digits'] = None
```

```
In [33]: print(so.to_definition(c))
con c : 3.3333333333333335 * x + 1e-20 * ((x) ^ (2)) <= 30.00000000001;
```

You can reset the options as follows:

```
In [34]: del so.config['max_digits']
```

You can also create a new configuration to be used globally:

```
In [35]: so.config['myvalue'] = 2
```

All default configuration options are as follows:

- verbosity (default 3)
- max_digits (default 12)
- print_digits (default 6)
- default_sense (default so.minimization)
- default_bounds
- valid_outcomes

3.3 Sessions

3.3.1 CAS Sessions

A `swat.cas.connection.CAS` session is needed to solve optimization problems with *sasoptpy* by using SAS Viya optimization solvers. See the SAS documentation to learn more about CAS sessions and SAS Viya.

You can create a sample CAS Session as follows:

```
>>> import sasoptpy as so
>>> from swat import CAS
>>> s = CAS(hostname=cas_host, username=cas_username, password=cas_password, port=cas_
↪port)
>>> m = so.Model(name='demo', session=s)
>>> print(repr(m))
sasoptpy.Model(name='demo', session=CAS(hostname, port, username, protocol='cas',␣
↪name='py-session-1', session=session-no))
```

You can end the session and close the connection as follows:

```
>>> s.terminate()
```

3.3.2 SAS Sessions

A `saspy.SASsession` session is needed to solve optimization problems with *sasoptpy* by using SAS/OR solvers on SAS 9.4 clients.

You can create a sample SAS session as follows:

```
>>> import sasoptpy as so
>>> import saspy
>>> sas_session = saspy.SASsession(cfgname='winlocal')
>>> m = so.Model(name='demo', session=sas_session)
>>> print(repr(m))
sasoptpy.Model(name='demo', session=saspy.SASsession(cfgname='winlocal'))
```

It is possible to connect to a SAS session by using a configuration file

```
In [1]: sas = saspy.SASsession(cfgfile=config_file)
Using SAS Config named: sshsas
SAS Connection established. Subprocess id is 8719
```

```
In [2]: m = so.Model(name='demo', session=sas)
NOTE: Initialized model demo.
```

```
In [3]: print(m.get_session().sasver)
9.04.01M6P11072018
```

You can terminate the SAS session as follows:

```
In [4]: sas.endsas()
SAS Connection terminated. Subprocess id was 8719
```

3.4 Models

3.4.1 Creating a model

You can create an empty model by using the *Model* constructor:

```
In [1]: import sasoptpy as so

In [2]: m = so.Model(name='model1')
NOTE: Initialized model model1.
```

3.4.2 Adding new components to a model

Adding a variable:

```
In [3]: x = m.add_variable(name='x', vartype=so.BIN)

In [4]: print(m)
Model: [
  Name: model1
  Objective: MIN [0]
  Variables (1): [
    x
  ]
  Constraints (0): [
  ]
]

In [5]: y = m.add_variable(name='y', lb=1, ub=10)

In [6]: print(m)
Model: [
  Name: model1
  Objective: MIN [0]
  Variables (2): [
    x
    y
  ]
  Constraints (0): [
  ]
]
```

Adding a constraint:

```
In [7]: c1 = m.add_constraint(x + 2 * y <= 10, name='c1')

In [8]: print(m)
Model: [
  Name: model1
  Objective: MIN [0]
  Variables (2): [
    x
    y
  ]
  Constraints (1): [
```

(continues on next page)

(continued from previous page)

```
    x + 2 * y <=  10
  ]
]
```

3.4.3 Adding existing components to a model

A new model can use existing variables. The typical way to include a variable is to use the `Model.include()` method:

```
In [9]: new_model = so.Model(name='new_model')
NOTE: Initialized model new_model.

In [10]: new_model.include(x, y)

In [11]: print(new_model)
Model: [
  Name: new_model
  Objective: MIN [0]
  Variables (2): [
    x
    y
  ]
  Constraints (0): [
  ]
]

In [12]: new_model.include(c1)

In [13]: print(new_model)
Model: [
  Name: new_model
  Objective: MIN [0]
  Variables (2): [
    x
    y
  ]
  Constraints (1): [
    x + 2 * y <=  10
  ]
]

In [14]: z = so.Variable(name='z', vartype=so.INT, lb=3)

In [15]: new_model.include(z)

In [16]: print(new_model)
Model: [
  Name: new_model
  Objective: MIN [0]
  Variables (3): [
    x
    y
    z
  ]
  Constraints (1): [
```

(continues on next page)

(continued from previous page)

```
    x + 2 * y <=  10
  ]
]
```

Note that variables are added to `Model` objects by reference. Therefore, after `Model.solve()` is called, the values of variables are replaced with optimal values.

3.4.4 Accessing components

You can get a list of model variables by using the `Model.get_variables()` method:

```
In [17]: print(m.get_variables())
[sasoptpy.Variable(name='x', lb=0, ub=1,  vartype='BIN'), sasoptpy.Variable(name='y',␣
↪lb=1, ub=10,  vartype='CONT')]
```

Similarly, you can access a list of constraints by using the `Model.get_constraints()` method:

```
In [18]: c2 = m.add_constraint(2 * x - y >= 1, name='c2')

In [19]: print(m.get_constraints())
[sasoptpy.Constraint(x + 2 * y <=  10, name='c1'), sasoptpy.Constraint(2 * x - y >= ␣
↪1, name='c2')]
```

To access a certain constraint by using its name, you can use the `Model.get_constraint()` method:

```
In [20]: print(m.get_constraint('c2'))
2 * x - y >=  1
```

3.4.5 Dropping components

You can drop a variable inside a model by using `Model.drop_variable()` method. Similarly, you can drop a set of variables by using the `Model.drop_variables()` method.

```
In [21]: m.drop_variable(y)

In [22]: print(m)
Model: [
  Name: model1
  Objective: MIN [0]
  Variables (1): [
    x
  ]
  Constraints (2): [
    x + 2 * y <=  10
    2 * x - y >=  1
  ]
]
```

```
In [23]: m.include(y)

In [24]: print(m)
Model: [
  Name: model1
```

(continues on next page)

(continued from previous page)

```
  Objective: MIN [0]
  Variables (2): [
    x
    y
  ]
  Constraints (2): [
    x + 2 * y <=  10
    2 * x - y >=  1
  ]
]
```

You can drop a constraint by using the `Model.drop_constraint()` method. Similarly, you can drop a set of constraints by using the `Model.drop_constraints()` method.

```
In [25]: m.drop_constraint(c1)

In [26]: m.drop_constraint(c2)

In [27]: print(m)
Model: [
  Name: model1
  Objective: MIN [0]
  Variables (2): [
    x
    y
  ]
  Constraints (0): [
  ]
]
```

```
In [28]: m.include(c1)

In [29]: print(m)
Model: [
  Name: model1
  Objective: MIN [0]
  Variables (2): [
    x
    y
  ]
  Constraints (1): [
    x + 2 * y <=  10
  ]
]
```

3.4.6 Copying a model

You can copy an existing model by including the `Model` object itself.

```
In [30]: copy_model = so.Model(name='copy_model')
NOTE: Initialized model copy_model.

In [31]: copy_model.include(m)

In [32]: print(copy_model)
Model: [
  Name: copy_model
  Objective: MIN [0]
  Variables (2): [
    x
    y
  ]
  Constraints (1): [
    x + 2 * y <=  10
  ]
]
```

Note that all variables and constraints are included by reference.

3.4.7 Solving a model

A model is solved by using the `Model.solve()` method. This method converts Python definitions into an MPS file and uploads it to a CAS server for the optimization action. The type of the optimization problem is determined based on the variable types and expressions.

```
>>> m.solve()
NOTE: Initialized model model_1
NOTE: Converting model model_1 to DataFrame
NOTE: Added action set 'optimization'.
...
NOTE: Optimal.
NOTE: Objective = 124.343.
NOTE: The Dual Simplex solve time is 0.01 seconds.
```

3.4.8 Solve options

Solver Options

You can pass both PROC OPTMODEL solve options and `solveLp`, `solveMilp` action options by using the `options` argument of the `Model.solve()` method.

```
>>> m.solve(options={'with': 'milp', 'maxtime': 600})
>>> m.solve(options={'with': 'lp', 'algorithm': 'ipm'})
```

The only special option for the `Model.solve()` method is `with`. If not passed, PROC OPTMODEL chooses a solver that depends on the problem type. Possible `with` options are listed in the SAS/OR documentation.

You can find specific solver options in the SAS Optimization documentation:

- LP solver options

- MILP solver options
- NLP solver options
- QP solver options
- BLACKBOX solver options

The `options` argument can also pass `solveLp` and `solveMilp` action options when `frame=True` is used when calling the `Model.solve()` method.

- solveLp options
- solveMilp options

Package Options

Besides the `options` argument, you can pass following arguments into the `Model.solve()` method:

- name: Name of the uploaded problem information
- drop: Option for dropping the data from server after the solve
- replace: Option for replacing an existing data with the same name
- primalin: Option for using the current values of the variables as an initial solution
- submit: Option for calling the CAS / SAS action
- frame: Option for using frame (MPS) method (if False, it uses OPTMODEL)
- verbose: Option for printing the generated OPTMODEL code before solve

When `primalin` argument is `True`, it grabs `Variable` objects `_init` field. You can modify this field by using the `Variable.set_init()` method.

3.4.9 Getting solutions

After the solve is completed, all variable and constraint values are parsed automatically. You can access a summary of the problem by using the `Model.get_problem_summary()` method, and a summary of the solution by using the `Model.get_solution_summary()` method.

To print the values of any object, you can use the `get_solution_table()` method:

```
>>> print(so.get_solution_table(x, y))
```

All variables and constraints passed into this method are returned based on their indices. See *Examples* for more details.

3.4.10 Tuning MILP model parameters

SAS Optimization solvers provide a variety of settings. However, it might be difficult to find the best settings for a given model. In order to compare and obtain a good choice of parameters, you can use the *optimization.tune* action for mixed-integer linear optimization problems.

The `Model.tune_parameters()` method is a wrapper for the tune action. Consider the following knapsack problem example:

```
In [33]: def get_model():
   ....:     m = so.Model(name='knapsack_with_tuner', session=cas_conn)
   ....:     data = [
   ....:         ['clock', 8, 4, 3],
   ....:         ['mug', 10, 6, 5],
   ....:         ['headphone', 15, 7, 2],
   ....:         ['book', 20, 12, 10],
   ....:         ['pen', 1, 1, 15]
   ....:     ]
   ....:     df = pd.DataFrame(data, columns=['item', 'value', 'weight', 'limit']).set_
↪index(['item'])
   ....:     ITEMS = df.index
   ....:     value = df['value']
   ....:     weight = df['weight']
   ....:     limit = df['limit']
   ....:     total_weight = 55
   ....:     get = m.add_variables(ITEMS, name='get', vartype=so.INT)
   ....:     m.add_constraints((get[i] <= limit[i] for i in ITEMS), name='limit_con')
   ....:     m.add_constraint(so.quick_sum(weight[i] * get[i] for i in ITEMS) <= total_
↪weight, name='weight_con')
   ....:     total_value = so.quick_sum(value[i] * get[i] for i in ITEMS)
   ....:     m.set_objective(total_value, name='total_value', sense=so.MAX)
   ....:     return m
   ....:

In [34]: m = get_model()
NOTE: Initialized model knapsack_with_tuner.
```

For this problem, you can compare configurations as follows:

```
In [35]: results = m.tune_parameters(tunerParameters={'maxConfigs': 10})
NOTE: Added action set 'optimization'.
NOTE: Uploading the problem DataFrame to the server.
NOTE: Cloud Analytic Services made the uploaded file available as table KNAPSACK_WITH_
↪TUNER in caslib CASUSER(casuser).
NOTE: The table KNAPSACK_WITH_TUNER has been created in caslib CASUSER(casuser) from␣
↪binary data uploaded to Cloud Analytic Services.
NOTE: Start to tune the MILP
         SolveCalls  Configurations    BestTime        Time
                  1               1        0.20        0.25
                  2               2        0.17        0.45
                  3               3        0.17        0.64
                  4               4        0.17        0.83
                  5               5        0.17        1.08
                  6               6        0.17        1.27
                  7               7        0.17        1.47

`Model.tune_parameters()` accepts three main arguments

- milpParameters
- tunerParameters
- tuningParameters

For a full set of tuning parameters and acceptable values of these arguments, see the SAS Optimization documentation[1].

For the example problem, you can tune the *presolver*, *cutStrategy*, and *strongIter* settings, by using initial values and candidate values, and limit the maximum number of configurations and maximum running time as follows:

[1] https://go.documentation.sas.com/?cdcId=pgmsascdc&cdcVersion=9.4_3.5&docsetId=casactmopt&docsetTarget=casactmopt_optimization_details37.htm

```
In [37]: results = m.tune_parameters(
   ....:     milpParameters={'maxtime': 10},
   ....:     tunerParameters={'maxConfigs': 20, 'logfreq': 5},
   ....:     tuningParameters=[
   ....:         {'option': 'presolver', 'initial': 'none', 'values': ['basic',
↪'aggressive', 'none']},
   ....:         {'option': 'cutStrategy'},
   ....:         {'option': 'strongIter', 'initial': -1, 'values': [-1, 100, 1000]}
   ....:     ])
   ....:

```

You can retrieve full details by using the `Model.get_tuner_results()` method.

3.5 Model components

In this section, several model components are discussed with examples. See *Examples* to learn more about how you can use these components to define optimization models.

3.5.1 Expressions

`Expression` objects represent linear and nonlinear mathematical expressions in *sasoptpy*.

Creating expressions

You can create an `Expression` object as follows:

```
In [1]: profit = so.Expression(5 * sales - 3 * material, name='profit')

In [2]: print(repr(profit))
sasoptpy.Expression(exp = 5 * sales - 3 * material, name='profit')
```

Nonlinear expressions

`Expression` objects are linear by default. It is possible to create nonlinear expressions, but there are some limitations.

```
In [3]: nonexp = sales ** 2 + (1 / material) ** 3

In [4]: print(nonexp)
(sales) ** (2) + ((1) / (material)) ** (3)
```

Currently, it is not possible to get or print values of nonlinear expressions. Moreover, if your model includes a nonlinear expression, you need to use SAS Viya 3.4 or later or any SAS version for solving your problem.

To use mathematical operations, you need to import *sasoptpy.math* functions.

Mathematical expressions

sasoptpy provides mathematical functions for generating mathematical expressions to be used in optimization models.

You need to import *sasoptpy.math* to your code to start by using these functions. Available mathematical functions are listed in *Math Functions*.

```
In [5]: import sasoptpy.math as sm

In [6]: newexp = sm.max(sales, 10) ** 2

In [7]: print(newexp._expr())
(max(sales , 10)) ^ (2)
```

```
In [8]: import sasoptpy.math as sm

In [9]: angle = so.Variable(name='angle')

In [10]: newexp = sm.sin(angle) ** 2 + sm.cos(angle) ** 2

In [11]: print(newexp._expr())
(sin(angle)) ^ (2) + (cos(angle)) ^ (2)
```

Operations

Getting the current value

After the solve is completed, you can obtain the current value of an expression by using the *Expression.get_value()* method:

```
>>> print(profit.get_value())
42.0
```

Getting the dual value

You can retrieve the dual values of *Expression* objects by using *Variable.get_dual()* and `Constraint.get_dual()` methods.

```
>>> m.solve()
>>> ...
>>> print(x.get_dual())
1.0
```

Addition

There are two ways to add elements to an expression. The first and simpler way creates a new expression at the end:

```
In [12]: tax = 0.5

In [13]: profit_after_tax = profit - tax
```

```
In [14]: print(repr(profit_after_tax))
sasoptpy.Expression(exp = 5 * sales - 3 * material - 0.5, name=None)
```

The second way, *Expression.add()* method, takes two arguments: the element to be added and the sign (1 or -1):

```
In [15]: profit_after_tax = profit.add(tax, sign=-1)
```

```
In [16]: print(profit_after_tax)
5 * sales - 3 * material - 0.5
```

```
In [17]: print(repr(profit_after_tax))
sasoptpy.Expression(exp = 5 * sales - 3 * material - 0.5, name=None)
```

If the expression is a temporary one, the addition is performed in place.

Multiplication

You can multiply expressions with scalar values:

```
In [18]: investment = profit.mult(0.2)

In [19]: print(investment)
sales - 0.6 * material
```

Summation

For faster summations compared to Python's native `sum` function, *sasoptpy* provides `sasoptpy.quick_sum()`.

```
In [20]: import time

In [21]: x = m.add_variables(1000, name='x')
```

```
In [22]: t0 = time.time()

In [23]: e = so.quick_sum(2 * x[i] for i in range(1000))

In [24]: print(time.time()-t0)
0.16195154190063477
```

```
In [25]: t0 = time.time()

In [26]: f = sum(2 * x[i] for i in range(1000))

In [27]: print(time.time()-t0)
1.0568652153015137
```

Renaming an expression

You can rename expressions by using the `Expression.set_name()` method:

```
In [28]: e = so.Expression(x[5] + 2 * x[6], name='e1')

In [29]: print(repr(e))
sasoptpy.Expression(exp = x[5] + 2 * x[6], name='e1')
```

```
In [30]: e.set_name('e2');

In [31]: print(repr(e))
sasoptpy.Expression(exp = x[5] + 2 * x[6], name='e2')
```

Copying an expression

You can copy an `Expression` by using the `Expression.copy()` method:

```
In [32]: copy_profit = profit.copy(name='copy_profit')

In [33]: print(repr(copy_profit))
sasoptpy.Expression(exp = 5 * sales - 3 * material, name='copy_profit')
```

3.5.2 Objective Functions

Setting and getting an objective function

You can use any valid `Expression` as the objective function of a model. You can also use an existing expression as an objective function by using the `Model.set_objective()` method. The objective function of a model can be obtained by using the `Model.get_objective()` method.

```
>>> profit = so.Expression(5 * sales - 2 * material, name='profit')
>>> m.set_objective(profit, so.MAX)
>>> print(m.get_objective())
 -  2.0 * material  +  5.0 * sales
```

Getting the value

After a solve, you can retrieve the objective value by using the `Model.get_objective_value()` method.

```
>>> m.solve()
>>> print(m.get_objective_value())
42.0
```

3.5.3 Variables

Creating variables

You can create variables either standalone or inside a model.

Creating a variable outside a model

The first way to create a variable uses the default constructor.

```
>>> x = so.Variable(vartype=so.INT, ub=5, name='x')
```

When created separately, a variable needs to be included (or added) inside the model:

```
>>> y = so.Variable(name='y', lb=5)
>>> m.add_variable(y)
```

Equivalently, you could do this in one step:

```
>>> y = m.add_variable(name='y', lb=5)
```

Creating a variable inside a model

The second way is to use `Model.add_variable()`. This method creates a `Variable` object and returns a pointer.

```
>>> x = m.add_variable(vartype=so.INT, ub=5, name='x')
```

Arguments

There are three types of variables: continuous variables, integer variables, and binary variables. Continuous variables are the default type and you can specify it by using the `vartype=so.CONT` argument. You can create Integer variables and binary variables by using the `vartype=so.INT` and `vartype=so.BIN` arguments, respectively.

The default lower bound for variables is 0, and the upper bound is infinity. Name is a required argument.

Changing bounds

The *Variable.set_bounds()* method changes the bounds of a variable.

```
>>> x = so.Variable(name='x', lb=0, ub=20)
>>> print(repr(x))
sasoptpy.Variable(name='x', lb=0, ub=20, vartype='CONT')
>>> x.set_bounds(lb=5, ub=15)
>>> print(repr(x))
sasoptpy.Variable(name='x', lb=5, ub=15, vartype='CONT')
```

Setting initial values

You can pass the initial values of variables to the solvers for certain problems. The *Variable.set_init()* method changes the initial value for variables. You can set this value at the creation of the variable as well.

```
>>> x.set_init(5)
>>> print(repr(x))
sasoptpy.Variable(name='x', ub=20, init=5,  vartype='CONT')
```

Working with a set of variables

You can create a set of variables by using single or multiple indices. Valid index sets include list, dict, and `pandas.Index` objects. See *Handling Data* for more information about allowed index types.

Creating a set of variables outside a model

```
>>> production = VariableGroup(PERIODS, vartype=so.INT, name='production',
                               lb=min_production)
>>> print(repr(production))
sasoptpy.VariableGroup(['Period1', 'Period2', 'Period3'], name='production')
>>> m.include(production)
```

Creating a set of variables inside a model

```
>>> production = m.add_variables(PERIODS, vartype=so.INT,
                                 name='production', lb=min_production)
>>> print(production)
>>> print(repr(production))
Variable Group (production) [
  [Period1: production['Period1',]]
  [Period2: production['Period2',]]
  [Period3: production['Period3',]]
]
sasoptpy.VariableGroup(['Period1', 'Period2', 'Period3'],
name='production')
```

3.5.4 Constraints

Creating constraints

Similar to *Variable* objects, you can create *Constraint* objects inside or outside optimization models.

Creating a constraint outside a model

```
>>> c1 = so.Constraint(3 * x - 5 * y <= 10, name='c1')
>>> print(repr(c1))
sasoptpy.Constraint( -  5.0 * y  +  3.0 * x  <=  10, name='c1')
```

Creating a constraint inside a model

```
>>> c1 = m.add_constraint(3 * x - 5 * y <= 10, name='c1')
>>> print(repr(c1))
sasoptpy.Constraint( -  5.0 * y  +  3.0 * x  <=  10, name='c1')
```

Modifying variable coefficients

You can update the coefficient of a variable inside a constraint by using the *Constraint.update_var_coef()* method:

```
>>> c1 = so.Constraint(exp=3 * x - 5 * y <= 10, name='c1')
>>> print(repr(c1))
sasoptpy.Constraint( -  5.0 * y  +  3.0 * x  <=  10, name='c1')
>>> c1.update_var_coef(x, -1)
>>> print(repr(c1))
sasoptpy.Constraint( -  5.0 * y  -  x  <=  10, name='c1')
```

Working with a set of constraints

You can add a set of constraints by using single or multiple indices. Valid index sets include list, dict, and `pandas.Index` objects. See *Handling Data* for more information about allowed index types.

Creating a set of constraints outside a model

```
>>> z = so.VariableGroup(2, ['a', 'b', 'c'], name='z', lb=0, ub=10)
>>> cg = so.ConstraintGroup((2 * z[i, j] + 3 * z[i-1, j] >= 2 for i in
                             [1] for j in ['a', 'b', 'c']), name='cg')
>>> print(cg)
Constraint Group (cg) [
  [(1, 'a'):  3.0 * z[0, 'a']  +  2.0 * z[1, 'a']  >=  2]
  [(1, 'b'):  3.0 * z[0, 'b']  +  2.0 * z[1, 'b']  >=  2]
  [(1, 'c'):  2.0 * z[1, 'c']  +  3.0 * z[0, 'c']  >=  2]
]
```

Creating a set of constraints inside a model

```
>>> z = so.VariableGroup(2, ['a', 'b', 'c'], name='z', lb=0, ub=10)
>>> cg2 = m.add_constraints((2 * z[i, j] + 3 * z[i-1, j] >= 2 for i in
                              [1] for j in ['a', 'b', 'c']), name='cg2')
>>> print(cg2)
Constraint Group (cg2) [
  [(1, 'a'):  2.0 * z[1, 'a']  +  3.0 * z[0, 'a']  >=  2]
```

(continues on next page)

(continued from previous page)

```
  [(1, 'b'):  3.0 * z[0, 'b']  +  2.0 * z[1, 'b']  >=  2]
  [(1, 'c'):  2.0 * z[1, 'c']  +  3.0 * z[0, 'c']  >=  2]
]
```

Range constraints

You can give a range for an expression by using a list of two value (lower and upper bound) with an == sign:

```
>>> x = m.add_variable(name='x')
>>> y = m.add_variable(name='y')
>>> c1 = m.add_constraint(x + 2*y == [2,9], name='c1')
>>> print(repr(c1))
sasoptpy.Constraint( x + 2.0 * y  ==  [2, 9], name='c1')
```

3.6 Workspaces

One of the most powerful features of SAS Optimization and PROC OPTMODEL is the ability to combine several optimization models in a single call. You can read a common data set once, or parallelize solve steps for similar subproblems by using this ability.

The newly introduced `Workspace` provides this ability in a familiar syntax. Compared to `Model` objects, a `Workspace` can consist of several models and is able to use server-side data and OPTMODEL statements in a more detailed way.

3.6.1 Creating a workspace

A `Workspace` should be called by using the *with* keyword of Python as follows:

```
>>> with so.Workspace('my_workspace') as w:
>>>     ...
```

You can define several models in the same workspace, and solve problems multiple times. All the statements are sent to the server after `Workspace.submit()` is called.

3.6.2 Adding components

Unlike `Model` objects, where components are added explicitly, objects defined inside a `Workspace` are added automatically.

For example, adding a new variable is performed as follows:

```
In [1]: with so.Workspace(name='my_workspace') as w:
   ...:     x = so.Variable(name='x', vartype=so.integer)
   ...:
```

You can display contents of a workspace by using the `Workspace.to_optmodel()` method:

```
In [2]: print(w.to_optmodel())
proc optmodel;
   var x integer;
quit;
```

See the following full example where data are loaded into the server, and a problem is solved by using a Workspace:

Create CAS session:

```
In [3]: import os

In [4]: hostname = os.getenv('CASHOST')

In [5]: port = os.getenv('CASPORT')

In [6]: from swat import CAS

In [7]: cas_conn = CAS(hostname, port)

In [8]: import sasoptpy as so

In [9]: import pandas as pd
```

Upload data:

```
In [10]: def send_data():
   ....:     data = [
   ....:         ['clock', 8, 4, 3],
   ....:         ['mug', 10, 6, 5],
   ....:         ['headphone', 15, 7, 2],
   ....:         ['book', 20, 12, 10],
   ....:         ['pen', 1, 1, 15]
   ....:     ]
   ....:     df = pd.DataFrame(data, columns=['item', 'value', 'weight', 'limit'])
   ....:     cas_conn.upload_frame(df, casout={'name': 'mydata', 'replace': True})
   ....: send_data()
   ....:
NOTE: Cloud Analytic Services made the uploaded file available as table MYDATA in␣
↪caslib CASUSER(casuser).
NOTE: The table MYDATA has been created in caslib CASUSER(casuser) from binary data␣
↪uploaded to Cloud Analytic Services.
```

Model workspace:

```
In [11]: from sasoptpy.actions import read_data, solve

In [12]: def create_workspace():
   ....:     with so.Workspace('my_knapsack', session=cas_conn) as w:
   ....:         items = so.Set(name='ITEMS', settype=so.string)
   ....:         value = so.ParameterGroup(items, name='value')
   ....:         weight = so.ParameterGroup(items, name='weight')
   ....:         limit = so.ParameterGroup(items, name='limit')
   ....:         total_weight = so.Parameter(name='total_weight', value=55)
   ....:         read_data(
   ....:             table='mydata', index={'target': items, 'key': ['item']},
   ....:             columns=[value, weight, limit]
   ....:         )
   ....:         get = so.VariableGroup(items, name='get', vartype=so.integer, lb=0)
   ....:         limit_con = so.ConstraintGroup((get[i] <= limit[i] for i in items),
   ....:                                        name='limit_con')
   ....:         weight_con = so.Constraint(
   ....:             so.expr_sum(weight[i] * get[i] for i in items) <= total_weight,
   ....:             name='weight_con')
```

(continues on next page)

(continued from previous page)

```
   ....:        total_value = so.Objective(
   ....:           so.expr_sum(value[i] * get[i] for i in items), name='total_value',
   ....:           sense=so.maximize)
   ....:        solve()
   ....:     return w
   ....:

In [13]: my_workspace = create_workspace()
```

Print content:

```
In [14]: print(so.to_optmodel(my_workspace))
proc optmodel;
   set <str> ITEMS;
   num value {ITEMS};
   num weight {ITEMS};
   num limit {ITEMS};
   num total_weight = 55;
   read data mydata into ITEMS=[item] value weight limit;
   var get {{ITEMS}} integer >= 0;
   con limit_con {o72 in ITEMS} : get[o72] - limit[o72] <= 0;
   con weight_con : total_weight - (sum {i in ITEMS} (weight[i] * get[i])) >= 0;
   max total_value = sum {i in ITEMS} (value[i] * get[i]);
   solve;
quit;
```

Submit:

```
In [15]: my_workspace.submit()

```

3.6.3 Abstract actions

As shown in the previous example, a *Workspace* can have statements such as *actions.read_data()* and *actions.solve()*.

These statements are called "Abstract Statements" and are fully supported inside *Workspace* objects.

Adding abstract actions

You can import abstract actions through *sasoptpy.actions* as follows:

```
>>> from sasoptpy.actions import read_data, create_data
```

These abstract actions are performed on the server side by generating equivalent OPTMODEL code at execution.

Grabbing results

In order to solve a problem, you need to use the *actions.solve()* function explicitly. Because *Workspace* objects allow several models and solve statements to be included, each of these solve statements are retrieved separately. You can return the solution after each solve by using the `actions.print()` function or creating a table by using the *actions.create_data()* function.

See the following example where a parameter is changed and the same problem solved twice:

```
In [16]: from sasoptpy.actions import read_data, solve, print_item

In [17]: def create_multi_solve_workspace():
   ....:     with so.Workspace('my_knapsack', session=cas_conn) as w:
   ....:         items = so.Set(name='ITEMS', settype=so.string)
   ....:         value = so.ParameterGroup(items, name='value')
   ....:         weight = so.ParameterGroup(items, name='weight')
   ....:         limit = so.ParameterGroup(items, name='limit')
   ....:         total_weight = so.Parameter(name='total_weight', init=55)
   ....:         read_data(table='mydata', index={'target': items, 'key': ['item']},␣
↪columns=[value, weight, limit])
   ....:         get = so.VariableGroup(items, name='get', vartype=so.integer, lb=0)
   ....:         limit_con = so.ConstraintGroup((get[i] <= limit[i] for i in items),␣
↪name='limit_con')
   ....:         weight_con = so.Constraint(
   ....:             so.expr_sum(weight[i] * get[i] for i in items) <= total_weight,␣
↪name='weight_con')
   ....:         total_value = so.Objective(so.expr_sum(value[i] * get[i] for i in␣
↪items), name='total_value', sense=so.MAX)
```

(continues on next page)

(continued from previous page)

```

List of abstract actions

A list of abstract actions is available in the *API section*.

3.7 Handling Data

sasoptpy can work with native Python types and *pandas* objects for all data operations. Among *pandas* object types, *sasoptpy* works with `pandas.DataFrame` and `pandas.Series` objects to construct and manipulate model components.

3.7.1 Indices

Methods like `Model.add_variables()` can utilize native Python object types like list and range as variable and constraint indices. You can use `pandas.Index` objects as indices as well.

List

```
In [1]: m = so.Model(name='demo')
NOTE: Initialized model demo.

In [2]: SEASONS = ['Fall', 'Winter', 'Spring', 'Summer']

In [3]: prod_lb = {'Fall': 100, 'Winter': 200, 'Spring': 100, 'Summer': 400}

In [4]: production = m.add_variables(SEASONS, lb=prod_lb, name='production')

In [5]: print(production)
Variable Group (production) [
  [Fall: production[Fall]]
  [Winter: production[Winter]]
  [Spring: production[Spring]]
  [Summer: production[Summer]]
]
```

```
In [6]: print(repr(production['Summer']))
sasoptpy.Variable(name='production[Summer]', lb=400,  vartype='CONT')
```

Note that if a list is being used as the index set, associated fields like *lb*, *ub* should be accessible by using the index keys. Accepted types are dict and `pandas.Series`.

Range

```
In [7]: link = m.add_variables(range(3), range(2), vartype=so.BIN, name='link')

In [8]: print(link)
Variable Group (link) [
  [(0, 0): link[0, 0]]
  [(0, 1): link[0, 1]]
  [(1, 0): link[1, 0]]
  [(1, 1): link[1, 1]]
  [(2, 0): link[2, 0]]
  [(2, 1): link[2, 1]]
]
```

```
In [9]: print(repr(link[2, 1]))
sasoptpy.Variable(name='link[2,1]', lb=0, ub=1,  vartype='BIN')
```

pandas.Index

```
In [10]: import pandas as pd

In [11]: p_data = [[3, 5, 9],
   ....:            [0, -1, 14],
   ....:            [5, 6, 20]]
   ....:

In [12]: df = pd.DataFrame(p_data, columns=['c1', 'col_lb', 'col_ub'])

In [13]: x = m.add_variables(df.index, lb=df['c1'], vartype=so.INT, name='x')
```

```
In [14]: print(x)
Variable Group (x) [
  [0: x[0]]
  [1: x[1]]
  [2: x[2]]
]
```

```
In [15]: df2 = df.set_index([['r1', 'r2', 'r3']])

In [16]: y = m.add_variables(df2.index, lb=df2['col_lb'], ub=df2['col_ub'], name='y')
```

```
In [17]: print(y)
Variable Group (y) [
  [r1: y[r1]]
  [r2: y[r2]]
  [r3: y[r3]]
]
```

```
In [18]: print(repr(y['r1']))
sasoptpy.Variable(name='y[r1]', lb=5, ub=9,  vartype='CONT')
```

Set

sasoptpy can work with data on the server and generate abstract expressions. For this purpose, you can use `Set` objects to represent PROC OPTMODEL sets.

```
In [19]: m2 = so.Model(name='m2')
NOTE: Initialized model m2.

In [20]: I = m2.add_set(name='I')

In [21]: u = m2.add_variables(I, name='u')

In [22]: print(I, u)
I Variable Group (u) [
]
```

See *Workflows* for more information on working with server-side models.

3.7.2 Data

sasoptpy can work with both client-side and server-side data. Here are some options to load data into the optimization models.

pandas DataFrame

`pandas.DataFrame` is the preferred object type when passing data into *sasoptpy* models.

```
In [23]: data = [
   ....:     ['clock', 8, 4, 3],
   ....:     ['mug', 10, 6, 5],
   ....:     ['headphone', 15, 7, 2],
   ....:     ['book', 20, 12, 10],
   ....:     ['pen', 1, 1, 15]
   ....:     ]
   ....:

In [24]: df = pd.DataFrame(data, columns=['item', 'value', 'weight', 'limit']).set_
↪index(['item'])

In [25]: get = so.VariableGroup(df.index, ub=df['limit'], name='get')

In [26]: print(get)
Variable Group (get) [
  [clock: get[clock]]
  [mug: get[mug]]
  [headphone: get[headphone]]
  [book: get[book]]
  [pen: get[pen]]
]
```

Dictionaries

You can use lists and dictionaries in expressions and when creating variables.

```
In [27]: items = ['clock', 'mug', 'headphone', 'book', 'pen']

In [28]: limits = {'clock': 3, 'mug': 5, 'headphone': 2, 'book': 10, 'pen': 15}

In [29]: get2 = so.VariableGroup(items, ub=limits, name='get2')

In [30]: print(get2)
Variable Group (get2) [
  [clock: get2[clock]]
  [mug: get2[mug]]
  [headphone: get2[headphone]]
  [book: get2[book]]
  [pen: get2[pen]]
]
```

CASTable

When data are available on the server-side, you can pass a reference to the object. Note that, using `swat.cas.table.CASTable` and Abstract Data requires SAS Viya version 3.4 or later.

```
In [31]: m2 = so.Model(name='m2', session=session)
NOTE: Initialized model m2.
```

```
In [32]: table = session.upload_frame(df)
NOTE: Cloud Analytic Services made the uploaded file available as table TMP24OHK8WS␣
↪in caslib CASUSER(casuser).
NOTE: The table TMP24OHK8WS has been created in caslib CASUSER(casuser) from binary␣
↪data uploaded to Cloud Analytic Services.
```

```
In [33]: print(type(table), table)
<class 'swat.cas.table.CASTable'> CASTable('TMP24OHK8WS', caslib='CASUSER(casuser)')
```

```
In [34]: df = pd.DataFrame(data, columns=['item', 'value', 'weight', 'limit'])

In [35]: ITEMS = m.add_set(name='ITEMS')

In [36]: value = m.add_parameter(ITEMS, name='value')

In [37]: weight = m.add_parameter(ITEMS, name='weight')

In [38]: limit = m.add_parameter(ITEMS, name='limit')

In [39]: from sasoptpy.actions import read_data

In [40]: m.include(read_data(table=table, index={'target': ITEMS, 'key': None},
   ....:                         columns=[value, weight, limit]))
   ....:

In [41]: get3 = m2.add_variables(ITEMS, name='get3')

In [42]: print(get3)
Variable Group (get3) [
]
```

Abstract Data

If you would like to model your problem first and then load data, you can pass a string for the data sets that will be available later.

```
In [43]: from sasoptpy.actions import read_data

In [44]: m3 = so.Model(name='m3', session=session)
NOTE: Initialized model m3.

In [45]: ITEMS = m.add_set(name='ITEMS')

In [46]: limit = m.add_parameter(ITEMS, name='limit')

In [47]: m3.include(read_data(table='DF', index=['item'], columns=[limit]))
```

(continues on next page)

(continued from previous page)

```
In [48]: print(type(ITEMS), ITEMS)
<class 'sasoptpy.abstract.set.Set'> ITEMS
```

Note that the key set is created as a reference. You can later solve the problem after having the data available with the same name; for example, by using the *upload_frame* function.

```
In [49]: session.upload_frame(df, casout='DF')
NOTE: Cloud Analytic Services made the uploaded file available as table DF in caslib␣
↪CASUSER(casuser).
NOTE: The table DF has been created in caslib CASUSER(casuser) from binary data␣
↪uploaded to Cloud Analytic Services.
Out[49]: CASTable('DF', caslib='CASUSER(casuser)')
```

3.7.3 Operations

You can use lists, `pandas.Series`, and `pandas.DataFrame` objects for mathematical operations such as `VariableGroup.mult()`.

```
In [50]: sd = [3, 5, 6]

In [51]: z = m.add_variables(3, name='z')
```

```
In [52]: print(z)
Variable Group (z) [
  [0: z[0]]
  [1: z[1]]
  [2: z[2]]
]
```

```
In [53]: print(repr(z))
sasoptpy.VariableGroup([0, 1, 2], name='z')
```

```
In [54]: e1 = z.mult(sd)

In [55]: print(e1)
3 * z[0] + 5 * z[1] + 6 * z[2]
```

```
In [56]: ps = pd.Series(sd)

In [57]: e2 = z.mult(ps)

In [58]: print(e2)
3 * z[0] + 5 * z[1] + 6 * z[2]
```

3.8 Workflows

sasoptpy can work with both client-side data and server-side data. Some limitations to the functionalities might apply in terms of which workflow is being used. In this section, the overall flow of the package is explained.

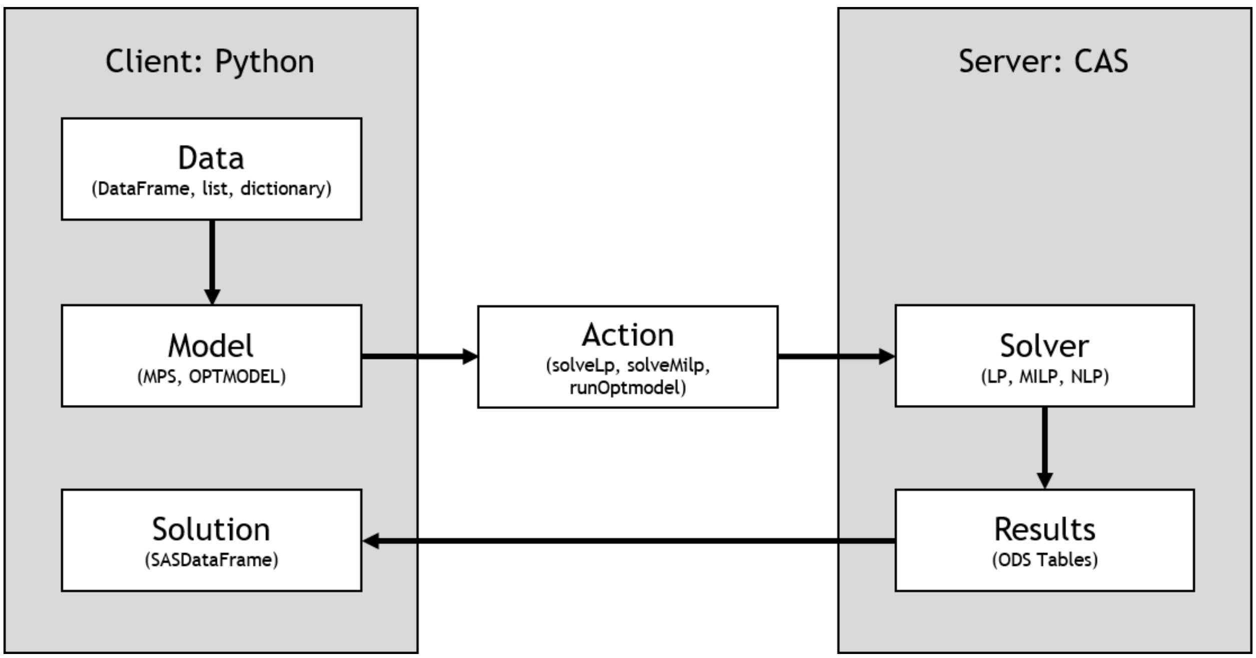
3.8.1 Client-side models

If the data are on the client-side (Python), then a concrete model is generated on the client-side and uploaded by using one of the available CAS actions.

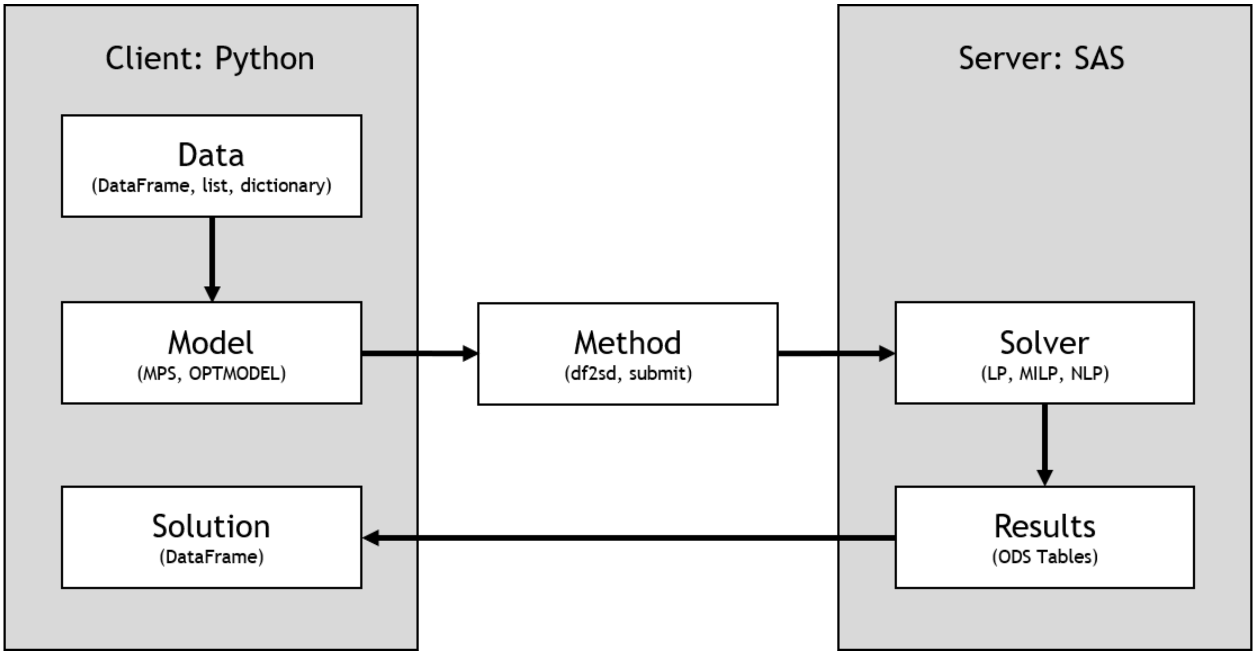
Using a client-side model brings several advantages, such as accessing variables, expressions, and constraints directly. You can do more intensive operations like filter data, sort values, change variable values, and print expressions more easily.

There are two main disadvantages of working with client-side models. First, if your model is relatively large, the generated MPS DataFrame or OPTMODEL code might allocate a large memory on your machine. Second, the information that needs to be passed from client to server might be larger compared to using a server-side model.

See the following representation of the client-side model workflow for CAS (Viya) servers:



See the following representation of the client-side model workflow for SAS clients:



Steps of modeling a simple knapsack problem are shown in the following subsections.

Reading data

```
In [1]: import sasoptpy as so

In [2]: import pandas as pd

In [3]: from swat import CAS

In [4]: session = CAS(hostname, port)

In [5]: m = so.Model(name='client_CAS', session=session)
NOTE: Initialized model client_CAS.

In [6]: data = [
   ...:     ['clock', 8, 4, 3],
   ...:     ['mug', 10, 6, 5],
   ...:     ['headphone', 15, 7, 2],
   ...:     ['book', 20, 12, 10],
   ...:     ['pen', 1, 1, 15]
   ...:     ]
   ...:

In [7]: df = pd.DataFrame(data, columns=['item', 'value', 'weight', 'limit'])

In [8]: ITEMS = df.index

In [9]: value = df['value']

In [10]: weight = df['weight']

In [11]: limit = df['limit']
```

(continues on next page)

(continued from previous page)

```
In [12]: total_weight = 55
```

```
In [13]: print(type(ITEMS), ITEMS)
<class 'pandas.core.indexes.range.RangeIndex'> RangeIndex(start=0, stop=5, step=1)
```

```
In [14]: print(type(total_weight), total_weight)
<class 'int'> 55
```

Here, you can obtain the column values one by one:

```
>>> df = df.set_index('item')
>>> ITEMS = df.index.tolist()
>>> value = df['value']
>>> weight = df['weight']
>>> limit = df['limit']
```

Model

```
# Variables
In [15]: get = m.add_variables(ITEMS, name='get', vartype=so.INT, lb=0)

# Constraints
In [16]: m.add_constraints((get[i] <= limit[i] for i in ITEMS), name='limit_con');

In [17]: m.add_constraint(
   ....:     so.quick_sum(weight[i] * get[i] for i in ITEMS) <= total_weight,
   ....:     name='weight_con');
   ....:

# Objective
In [18]: total_value = so.expr_sum(value[i] * get[i] for i in ITEMS)

In [19]: m.set_objective(total_value, name='total_value', sense=so.MAX);

# Solve
In [20]: m.solve(verbose=True)
NOTE: Added action set 'optimization'.
NOTE: Converting model client_CAS to OPTMODEL.
   var get {{0,1,2,3,4}} integer >= 0;
   con limit_con_0 : get[0] <= 3;
   con limit_con_1 : get[1] <= 5;
   con limit_con_2 : get[2] <= 2;
   con limit_con_3 : get[3] <= 10;
   con limit_con_4 : get[4] <= 15;
   con weight_con : 4 * get[0] + 6 * get[1] + 7 * get[2] + 12 * get[3] + get[4] <= 55;
   max total_value = 8 * get[0] + 10 * get[1] + 15 * get[2] + 20 * get[3] + get[4];
   solve;
   create data solution from [i]= {1.._NVAR_} var=_VAR_.name value=_VAR_ lb=_VAR_.lb␣

NOTE: The CAS table 'solutionSummary' in caslib 'CASUSER(casuser)' has 18 rows and 4␣
↪columns.
NOTE: The CAS table 'problemSummary' in caslib 'CASUSER(casuser)' has 20 rows and 4␣
↪columns.
Out[20]:
Selected Rows from Table SOLUTION

     i     var  value   lb             ub  rc
0  1.0  get[0]    2.0 -0.0  1.797693e+308 NaN
1  2.0  get[1]    5.0 -0.0  1.797693e+308 NaN
2  3.0  get[2]    2.0 -0.0  1.797693e+308 NaN
3  4.0  get[3]   -0.0 -0.0  1.797693e+308 NaN
4  5.0  get[4]    3.0 -0.0  1.797693e+308 NaN
```

You can display the generated OPTMODEL code at runtime by using the `verbose` option. Here, you can see the coefficient values of the parameters inside the model.

Parsing results

After the solve, the primal and dual solution tables are obtained. You can print the solution tables by using the *Model.get_solution()* method.

It is also possible to print the optimal solution by using the *get_solution_table()* function.

```
In [21]: print(m.get_solution())
Selected Rows from Table SOLUTION

     i     var  value   lb             ub  rc
0  1.0  get[0]    2.0 -0.0  1.797693e+308 NaN
```

(continues on next page)

(continued from previous page)

2  3.0  get[2]    2.0 -0.0  1.797693e+308 NaN
3  4.0  get[3]   -0.0 -0.0  1.797693e+308 NaN
4  5.0  get[4]    3.0 -0.0  1.797693e+308 NaN
```

```
In [22]: print(so.get_solution_table(get, key=ITEMS))
   get
0  2.0
1  5.0
2  2.0
3 -0.0
4  3.0
```

```
In [23]: print('Total value:', total_value.get_value())
Total value: 99.0
```

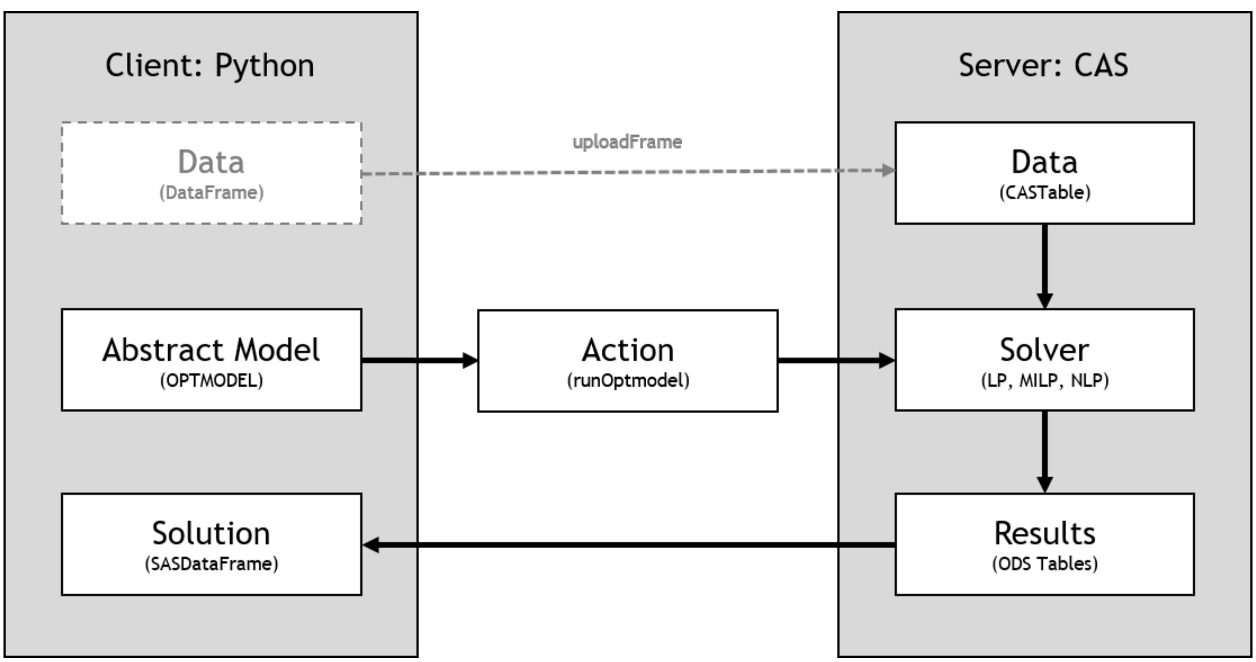
3.8.2 Server-side models

If the data are on the server-side (CAS or SAS), then an abstract model is generated on the client-side. This abstract model is later converted to PROC OPTMODEL code, which reads the data on the server.

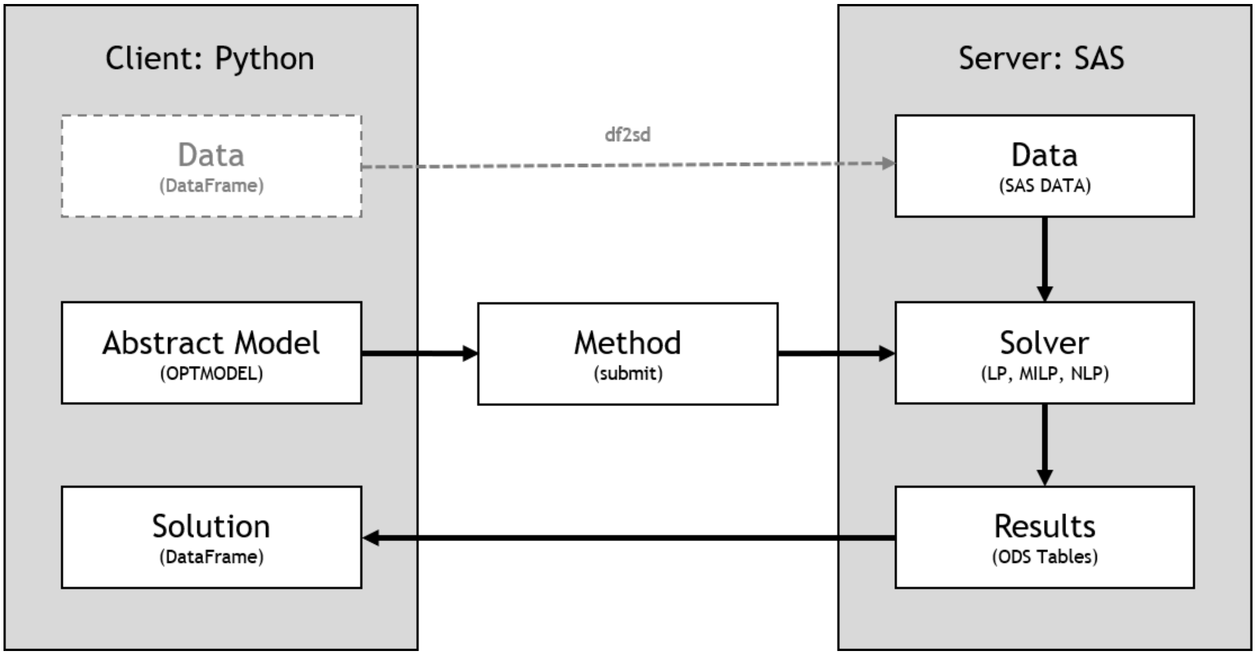
The main advantage of the server-side models is faster upload times compared to client-side. This is especially noticeable when using large numbers of variable and constraint groups.

The only disadvantage of using server-side models is that variables often need to be accessed directly from the resulting SASDataFrame objects. Because components of the models are abstract, accessing objects directly is often not possible.

See the following representation of the server-side model workflow for CAS (Viya) servers:



See the following representation of the server-side model workflow for SAS clients:



In the following subsections, the same example is solved by using server-side data.

Model

```
In [24]: from sasoptpy.actions import read_data

In [25]: m = so.Model(name='client_CAS', session=session)
NOTE: Initialized model client_CAS.
```

```
In [26]: cas_table = session.upload_frame(df, casout='data')
NOTE: Cloud Analytic Services made the uploaded file available as table DATA in␣
↪caslib CASUSER(casuser).
NOTE: The table DATA has been created in caslib CASUSER(casuser) from binary data␣
↪uploaded to Cloud Analytic Services.
```

```
In [27]: ITEMS = m.add_set(name='ITEMS', settype=so.STR)

In [28]: value = m.add_parameter(ITEMS, name='value')

In [29]: weight = m.add_parameter(ITEMS, name='weight')

In [30]: limit = m.add_parameter(ITEMS, name='limit')

In [31]: m.include(read_data(
   ....:     table=cas_table, index={'target':ITEMS, 'key': 'item'},
   ....:     columns=[value, weight, limit]))
   ....:

# Variables
In [32]: get = m.add_variables(ITEMS, name='get', vartype=so.INT, lb=0)

# Constraints
In [33]: m.add_constraints((get[i] <= limit[i] for i in ITEMS), name='limit_con');
```

(continues on next page)

(continued from previous page)

```
In [34]: m.add_constraint(
   ....:     so.quick_sum(weight[i] * get[i] for i in ITEMS) <= total_weight,
   ....:     name='weight_con');
   ....:
```

```
# Objective
In [35]: total_value = so.quick_sum(value[i] * get[i] for i in ITEMS)

In [36]: m.set_objective(total_value, name='total_value', sense=so.MAX);

# Solve
In [37]: m.solve(verbose=True)
NOTE: Added action set 'optimization'.
NOTE: Converting model client_CAS to OPTMODEL.
   set <str> ITEMS;
   num value {{ITEMS}};
   num weight {{ITEMS}};
   num limit {{ITEMS}};
   read data DATA into ITEMS=[item] value weight limit;
   var get {{ITEMS}} integer >= 0;
   con limit_con {o37 in ITEMS} : get[o37] - limit[o37] <= 0;
   con weight_con : sum {i in ITEMS} (weight[i] * get[i]) <= 55;
   max total_value = sum {i in ITEMS} (value[i] * get[i]);
   solve;
   create data solution from [i]= {1.._NVAR_} var=_VAR_.name value=_VAR_ lb=_VAR_.lb␣
↪ub=_VAR_.ub rc=_VAR_.rc;
   create data dual from [j] = {1.._NCON_} con=_CON_.name value=_CON_.body dual=_CON_.

1  2.0       get[clock]    3.0 -0.0  1.797693e+308 NaN
2  3.0   get[headphone]    2.0 -0.0  1.797693e+308 NaN
3  4.0         get[mug]   -0.0 -0.0  1.797693e+308 NaN
4  5.0         get[pen]    5.0 -0.0  1.797693e+308 NaN
```

Parsing results

```
# Print results
In [38]: print(m.get_solution())
Selected Rows from Table SOLUTION

     i              var  value   lb             ub  rc
0  1.0        get[book]    2.0 -0.0  1.797693e+308 NaN
1  2.0       get[clock]    3.0 -0.0  1.797693e+308 NaN
2  3.0   get[headphone]    2.0 -0.0  1.797693e+308 NaN
3  4.0         get[mug]   -0.0 -0.0  1.797693e+308 NaN
4  5.0         get[pen]    5.0 -0.0  1.797693e+308 NaN
```

```
In [39]: print('Total value:', m.get_objective_value())
Total value: 99.0
```

Because there is no direct access to expressions and variables, the optimal solution is printed by using the server response.

3.8.3 Limitations

- In SAS Viya, nonlinear models can be solved only by using the runOptmodel action, which requires the SAS Viya version to be 3.4 or later.
- User-defined decomposition blocks are available only in MPS mode, and therefore only work with client-side data.
- Mixed usage (client-side and server-side data) might not work in some cases. A quick fix would be transferring the data in either direction.

CHAPTER

FOUR

EXAMPLES

Examples are provided from SAS/OR documentation.

CHAPTER

FIVE

API REFERENCE

5.1 Core

5.1.1 Model

Constructor

Model(**kwargs)	Creates an optimization model

sasoptpy.Model

class Model(***kwargs*)

Bases: object

Creates an optimization model

Parameters

name [string] Name of the model

session [swat.cas.connection.CAS or saspy.SASsession, optional] CAS or SAS Session object

Examples

```
>>> from swat import CAS
>>> import sasoptpy as so
>>> s = CAS('cas.server.address', port=12345)
>>> m = so.Model(name='my_model', session=s)
NOTE: Initialized model my_model
```

```
>>> mip = so.Model(name='mip')
NOTE: Initialized model mip
```

Components

Model.get_name(self)	Returns model name
Model.set_session(self, session)	Sets the session of model (SAS Viya via swat or SAS 9.4 via saspy)
Model.get_session(self)	Returns the session of the model
Model.get_session_type(self)	Tests if the model session is defined and still active
Model.set_objective(self, expression, name)	Sets the objective function for the model
Model.append_objective(self, expression, name)	Appends a new objective to the model
Model.get_objective(self)	Returns the objective function as an Expression object
Model.get_all_objectives(self)	Returns a list of objectives in the model
Model.add_variable(self, name[, vartype, . . .])	Adds a new variable to the model
Model.add_variables(self, *argv[, name, . . .])	Adds a group of variables to the model
Model.add_implicit_variable(self[, argv, name])	Adds an implicit variable to the model
Model.get_variable(self, name)	Returns the reference to a variable in the model
Model.get_variables(self)	Returns a list of variables
Model.get_grouped_variables(self)	Get an ordered dictionary of variables, grouped based on creation
Model.get_implicit_variables(self)	Returns a list of implicit variables
Model.get_variable_coef(self, var)	Returns the objective value coefficient of a variable
Model.drop_variable(self, variable)	Drops a variable from the model
Model.drop_variables(self, variables)	Drops a variable group from the model
Model.add_constraint(self, c, name)	Adds a single constraint to the model
Model.add_constraints(self, argv[, name])	Adds a set of constraints to the model
Model.get_constraint(self, name)	Returns the reference to a constraint in the model
Model.get_constraints(self)	Returns a list of constraints in the model
Model.get_grouped_constraints(self)	Get an ordered dictionary of constraints, grouped based on creation
Model.drop_constraint(self, constraint)	Drops a constraint from the model
Model.drop_constraints(self, constraints)	Drops a constraint group from the model
Model.add_set(self, name[, init, value, settype])	Adds a set to the model
Model.add_parameter(self, *argv[, name, . . .])	Adds a parameter to the model
Model.add_statement(self, statement[, . . .])	Adds a PROC OPTMODEL statement to the model
Model.get_sets(self)	Returns a list of Set objects in the model
Model.get_parameters(self)	Returns a list of Parameter objects in the model
Model.get_statements(self)	Returns a list of all abstract statements inside the model.
Model.include(self, *argv)	Adds existing variables and constraints to a model

sasoptpy.Model.get_name

`Model.get_name(self)`
Returns model name

sasoptpy.Model.set_session

`Model.set_session(self, session)`
Sets the session of model (SAS Viya via swat or SAS 9.4 via saspy)

Parameters

session [`swat.cas.connection.CAS` or `saspy.SASsession`] CAS or SAS Session object

Notes

- Session of a model can be set at initialization. See *Model*.

sasoptpy.Model.get_session

`Model.get_session(self)`
Returns the session of the model

Returns

session [`swat.cas.connection.CAS` or `saspy.SASsession`] Session of the model, or None

sasoptpy.Model.get_session_type

`Model.get_session_type(self)`
Tests if the model session is defined and still active

Returns

session [string] 'CAS' for CAS sessions, 'SAS' for SAS sessions, None otherwise

sasoptpy.Model.set_objective

`Model.set_objective(self, expression, name, sense=None)`
Sets the objective function for the model

Parameters

expression [Expression] The objective function as an Expression

name [string] Name of the objective value

sense [string, optional] Objective value direction, 'MIN' or 'MAX'

Returns

objective [Expression] Objective function as an *Expression* object

See also:

Model.append_objective()

Notes

- Default objective sense is minimization (MIN)
- This method replaces the existing objective of the model. When working with multiple objectives, use *Model.append_objective()* method.

Examples

```
>>> profit = so.Expression(5 * sales - 2 * material, name='profit')
>>> m.set_objective(profit, so.MAX)
>>> print(m.get_objective())
 -  2.0 * material  +  5.0 * sales
```

```
>>> m.set_objective(4 * x - 5 * y, name='obj')
>>> print(repr(m.get_objective()))
sasoptpy.Expression(exp =  4.0 * x  -  5.0 * y , name='obj')
```

```
>>> f1 = m.set_objective(2 * x + y, sense=so.MIN, name='f1')
>>> f2 = m.append_objective( (x - y) ** 2, sense=so.MIN, name='f2')
>>> print(m.to_optmodel(options={'with': 'blackbox', 'obj': (f1, f2)}))
proc optmodel;
var x;
var y;
min f1 = 2 * x + y;
min f2 = (x - y) ^ (2);
solve with blackbox obj (f1 f2);
print _var_.name _var_.lb _var_.ub _var_ _var_.rc;
print _con_.name _con_.body _con_.dual;
quit;
```

sasoptpy.Model.append_objective

Model.**append_objective**(*self*, *expression*, *name*, *sense=None*)

Appends a new objective to the model

Parameters

expression [Expression] The objective function as an Expression

name [string] Name of the objective value

sense [string, optional] Objective value direction, 'MIN' or 'MAX'

Returns

objective [Expression] Objective function as an *Expression* object

See also:

Model.set_objective()

Notes

- Default objective sense is minimization (MIN)

Examples

```
>>> f1 = m.set_objective(2 * x + y, sense=so.MIN, name='f1')
>>> f2 = m.append_objective( (x - y) ** 2, sense=so.MIN, name='f2')
>>> print(m.to_optmodel(options={'with': 'blackbox', 'obj': (f1, f2)}))
proc optmodel;
var x;
var y;
min f1 = 2 * x + y;
min f2 = (x - y) ^ (2);
solve with blackbox obj (f1 f2);
print _var_.name _var_.lb _var_.ub _var_ _var_.rc;
print _con_.name _con_.body _con_.dual;
quit;
```

sasoptpy.Model.get_objective

`Model.`**`get_objective`**`(`*self*`)`

Returns the objective function as an `Expression` object

Returns

objective [Expression] Objective function

Examples

```
>>> m.set_objective(4 * x - 5 * y, name='obj')
>>> print(repr(m.get_objective()))
sasoptpy.Expression(exp =  4.0 * x  -  5.0 * y , name='obj')
```

sasoptpy.Model.get_all_objectives

`Model.`**`get_all_objectives`**`(`*self*`)`

Returns a list of objectives in the model

Returns

all_objectives [list] A list of `Objective` objects

Examples

```
>>> m = so.Model(name='test_set_get_objective')
>>> x = m.add_variable(name='x')
>>> obj1 = m.set_objective(2 * x, sense=so.MIN, name='obj1')
>>> obj2 = m.set_objective(5 * x, sense=so.MIN, name='obj2') # Overrides obj1
>>> obj3 = m.append_objective(10 * x, sense=so.MIN, name='obj3')
>>> assertEqual(m.get_all_objectives(), [obj2, obj3])
True
```

sasoptpy.Model.add_variable

Model.**add_variable**(*self*, *name*, *vartype=None*, *lb=None*, *ub=None*, *init=None*)

Adds a new variable to the model

New variables can be created via this method or existing variables can be added to the model.

Parameters

name [string, optional] Name of the variable to be created

vartype [string, optional] Type of the variable, either 'BIN', 'INT' or 'CONT'

lb [float, optional] Lower bound of the variable

ub [float, optional] Upper bound of the variable

init [float, optional] Initial value of the variable

Returns

var [Variable] Variable that is added to the model

See also:

Variable, *Model.include()*

Notes

- If argument *var* is not None, then all other arguments are ignored.
- A generic variable name is generated if name argument is None.

Examples

Adding a variable on the fly

```
>>> m = so.Model(name='demo')
>>> x = m.add_variable(name='x', vartype=so.INT, ub=10, init=2)
>>> print(repr(x))
NOTE: Initialized model demo
sasoptpy.Variable(name='x', lb=0, ub=10, init=2, vartype='INT')
```

Adding an existing variable to a model

```
>>> y = so.Variable(name='y', vartype=so.BIN)
>>> m = so.Model(name='demo')
>>> m.include(y)
```

sasoptpy.Model.add_variables

`Model.add_variables(self, *argv, name=None, vartype=None, lb=None, ub=None, init=None)`

Adds a group of variables to the model

Parameters

argv [list, dict, `pandas.Index`] Loop index for variable group

name [string, optional] Name of the variables

vartype [string, optional] Type of variables, *BIN*, *INT*, or *CONT*

lb [list, dict, `pandas.Series`] Lower bounds of variables

ub [list, dict, `pandas.Series`] Upper bounds of variables

init [list, dict, `pandas.Series`] Initial values of variables

See also:

`VariableGroup`, `Model.include()`

Notes

If *vg* argument is passed, all other arguments are ignored.

Examples

```
>>> production = m.add_variables(PERIODS, vartype=so.INT,
                                  name='production', lb=min_production)
>>> print(production)
>>> print(repr(production))
Variable Group (production) [
  [Period1: production['Period1',]]
  [Period2: production['Period2',]]
  [Period3: production['Period3',]]
]
sasoptpy.VariableGroup(['Period1', 'Period2', 'Period3'],
name='production')
```

sasoptpy.Model.add_implicit_variable

`Model.add_implicit_variable(self, argv=None, name=None)`

Adds an implicit variable to the model

Parameters

argv [Generator-type object] Generator object where each item is an entry

name [string, optional] Name of the implicit variable

Notes

- Based on whether generated by a regular expression or an abstract one, implicit variables may appear in generated OPTMODEL codes.

Examples

```
>>> x = m.add_variables(range(5), name='x')
>>> y = m.add_implicit_variable((
>>>     x[i] + 2 * x[i+1] for i in range(4)), name='y')
>>> print(y[2])
x[2] + 2 * x[3]
```

```
>>> I = m.add_set(name='I')
>>> z = m.add_implicit_variable((x[i] * 2 + 2 for i in I), name='z')
>>> print(z._defn())
impvar z {i_1 in I} = 2 * x[i_1] + 2;
```

sasoptpy.Model.get_variable

`Model.`**`get_variable`**(*self*, *name*)

Returns the reference to a variable in the model

Parameters

name [string] Name or key of the variable requested

Returns

variable [Variable] Reference to the variable

Examples

```
>>> m.add_variable(name='x', vartype=so.INT, lb=3, ub=5)
>>> var1 = m.get_variable('x')
>>> print(repr(var1))
sasoptpy.Variable(name='x', lb=3, ub=5, vartype='INT')
```

sasoptpy.Model.get_variables

`Model.`**`get_variables`**(*self*)

Returns a list of variables

Returns

variables [list] List of variables in the model

Examples

```
>>> x = m.add_variables(2, name='x')
>>> y = m.add_variable(name='y')
>>> print(m.get_variables())
[sasoptpy.Variable(name='x_0',  vartype='CONT'),
 sasoptpy.Variable(name='x_1',  vartype='CONT'),
 sasoptpy.Variable(name='y',  vartype='CONT')]
```

sasoptpy.Model.get_grouped_variables

Model.**get_grouped_variables**(*self*)

Get an ordered dictionary of variables, grouped based on creation

Returns

grouped_vars [OrderedDict] Dictionary of variables and variable groups in the model

See also:

Model.get_variables(), *Model.get_grouped_constraints()*

Examples

```
>>> m1 = so.Model(name='test_copy_model_1')
>>> x = m1.add_variable(name='x')
>>> y = m1.add_variables(2, name='y')
>>> vars = OrderedDict([('x', x), ('y', y)])
>>> self.assertEqual(m1.get_grouped_variables(), vars)
True
```

sasoptpy.Model.get_implicit_variables

Model.**get_implicit_variables**(*self*)

Returns a list of implicit variables

Returns

implicit_variables [list] List of implicit variables in the model

Examples

```
>>> m = so.Model(name='test_add_impvar')
>>> x = m.add_variables(5, name='x')
>>> y = m.add_implicit_variable((i * x[i] + x[i] ** 2 for i in range(5)),
                                name='y')
>>> assertEqual([y], m.get_implicit_variables())
True
```

sasoptpy.Model.get_variable_coef

`Model.get_variable_coef(self, var)`

Returns the objective value coefficient of a variable

Parameters

var [Variable or string] Variable whose objective value is requested or its name

Returns

coef [float] Objective value coefficient of the given variable

Examples

```
>>> x = m.add_variable(name='x')
>>> y = m.add_variable(name='y')
>>> m.set_objective(4 * x - 5 * y, name='obj', sense=so.MAX)
>>> print(m.get_variable_coef(x))
4.0
>>> print(m.get_variable_coef('y'))
-5.0
```

sasoptpy.Model.drop_variable

`Model.drop_variable(self, variable)`

Drops a variable from the model

Parameters

variable [Variable] The variable to be dropped from the model

See also:

Model.drop_variables()

Model.drop_constraint()

Model.drop_constraints()

Examples

```
>>> x = m.add_variable(name='x')
>>> y = m.add_variable(name='y')
>>> print(m.get_variable('x'))
 x
>>> m.drop_variable(x)
>>> print(m.get_variable('x'))
None
```

sasoptpy.Model.drop_variables

Model.**drop_variables**(*self*, *variables*)

Drops a variable group from the model

Parameters

variables [VariableGroup] The variable group to be dropped from the model

See also:

Model.drop_variable()

Model.drop_constraint()

Model.drop_constraints()

Examples

```
>>> x = m.add_variables(3, name='x')
>>> print(m.get_variables())
[sasoptpy.Variable(name='x_0',  vartype='CONT'),
 sasoptpy.Variable(name='x_1',  vartype='CONT')]
>>> m.drop_variables(x)
>>> print(m.get_variables())
[]
```

sasoptpy.Model.add_constraint

Model.**add_constraint**(*self*, *c*, *name*)

Adds a single constraint to the model

Parameters

c [Constraint] Constraint to be added to the model

name [string, optional] Name of the constraint

Returns

c [Constraint] Reference to the constraint

See also:

Constraint, *Model.include()*

Examples

```
>>> x = m.add_variable(name='x', vartype=so.INT, lb=0, ub=5)
>>> y = m.add_variables(3, name='y', vartype=so.CONT, lb=0, ub=10)
>>> c1 = m.add_constraint(x + y[0] >= 3, name='c1')
>>> print(c1)
 x  +  y[0]  >=  3
```

```
>>> c2 = m.add_constraint(x - y[2] == [4, 10], name='c2')
>>> print(c2)
 -  y[2]  +  x  =  [4, 10]
```

sasoptpy.Model.add_constraints

`Model.add_constraints(self, argv, name=None)`
Adds a set of constraints to the model

Parameters

argv [Generator-type object] List of constraints as a Generator-type object

name [string, optional] Name for the constraint group and individual constraint prefix

Returns

cg [ConstraintGroup] Reference to the ConstraintGroup

See also:

ConstraintGroup, *Model.include()*

Examples

```
>>> x = m.add_variable(name='x', vartype=so.INT, lb=0, ub=5)
>>> y = m.add_variables(3, name='y', vartype=so.CONT, lb=0, ub=10)
>>> c = m.add_constraints((x + 2 * y[i] >= 2 for i in [0, 1, 2]),
                          name='c')
>>> print(c)
Constraint Group (c) [
  [0:  2.0 * y[0]  +  x  >=  2]
  [1:  2.0 * y[1]  +  x  >=  2]
  [2:  2.0 * y[2]  +  x  >=  2]
]
```

```
>>> t = m.add_variables(3, 4, name='t')
>>> ct = m.add_constraints((t[i, j] <= x for i in range(3)
                           for j in range(4)), name='ct')
>>> print(ct)
Constraint Group (ct) [
  [(0, 0):  -  x  +  t[0, 0]  <=  0]
  [(0, 1):  t[0, 1]  -  x  <=  0]
  [(0, 2):  -  x  +  t[0, 2]  <=  0]
  [(0, 3):  t[0, 3]  -  x  <=  0]
  [(1, 0):  t[1, 0]  -  x  <=  0]
  [(1, 1):  t[1, 1]  -  x  <=  0]
  [(1, 2):  -  x  +  t[1, 2]  <=  0]
  [(1, 3):  -  x  +  t[1, 3]  <=  0]
  [(2, 0):  -  x  +  t[2, 0]  <=  0]
  [(2, 1):  t[2, 1]  -  x  <=  0]
  [(2, 2):  t[2, 2]  -  x  <=  0]
  [(2, 3):  t[2, 3]  -  x  <=  0]
]
```

sasoptpy.Model.get_constraint

`Model.get_constraint(self, name)`

Returns the reference to a constraint in the model

Parameters

name [string] Name of the constraint requested

Returns

constraint [Constraint] Reference to the constraint

Examples

```
>>> m.add_constraint(2 * x + y <= 15, name='c1')
>>> print(m.get_constraint('c1'))
2.0 * x  +  y  <=  15
```

sasoptpy.Model.get_constraints

`Model.get_constraints(self)`

Returns a list of constraints in the model

Returns

constraints [list] A list of Constraint objects

Examples

```
>>> m.add_constraint(x[0] + y <= 15, name='c1')
>>> m.add_constraints((2 * x[i] - y >= 1 for i in [0, 1]), name='c2')
>>> print(m.get_constraints())
[sasoptpy.Constraint( x[0]  +  y  <=  15, name='c1'),
 sasoptpy.Constraint( 2.0 * x[0]  -  y  >=  1, name='c2_0'),
 sasoptpy.Constraint( 2.0 * x[1]  -  y  >=  1, name='c2_1')]
```

sasoptpy.Model.get_grouped_constraints

`Model.get_grouped_constraints(self)`

Get an ordered dictionary of constraints, grouped based on creation

Returns

grouped_cons [OrderedDict] Dictionary of constraints and constraint groups in the model

See also:

Model.get_constraints(), *Model.get_grouped_variables()*

Examples

```
>>> m1 = so.Model(name='test_copy_model_1')
>>> x = m1.add_variable(name='x')
>>> y = m1.add_variables(2, name='y')
>>> c1 = m1.add_constraint(x + y[0] >= 2, name='c1')
>>> c2 = m1.add_constraints((x - y[i] <= 10 for i in range(2)), name='c2')
>>> cons = OrderedDict([('c1', c1), ('c2', c2)])
>>> self.assertEqual(m1.get_grouped_constraints(), cons)
True
```

sasoptpy.Model.drop_constraint

`Model.`**`drop_constraint`**(*self*, *constraint*)

Drops a constraint from the model

Parameters

constraint [Constraint] The constraint to be dropped from the model

See also:

`Model.drop_constraints()`

`Model.drop_variable()`

`Model.drop_variables()`

Examples

```
>>> c1 = m.add_constraint(2 * x + y <= 15, name='c1')
>>> print(m.get_constraint('c1'))
2 * x  +  y  <=  15
>>> m.drop_constraint(c1)
>>> print(m.get_constraint('c1'))
None
```

sasoptpy.Model.drop_constraints

`Model.`**`drop_constraints`**(*self*, *constraints*)

Drops a constraint group from the model

Parameters

constraints [ConstraintGroup] The constraint group to be dropped from the model

See also:

`Model.drop_constraints()`

`Model.drop_variable()`

`Model.drop_variables()`

Examples

```
>>> c1 = m.add_constraints((x[i] + y <= 15 for i in [0, 1]), name='c1')
>>> print(m.get_constraints())
[sasoptpy.Constraint( x[0]  +  y  <=  15, name='c1_0'),
 sasoptpy.Constraint( x[1]  +  y  <=  15, name='c1_1')]
>>> m.drop_constraints(c1)
>>> print(m.get_constraints())
[]
```

sasoptpy.Model.add_set

`Model.`**add_set**(*self*, *name*, *init=None*, *value=None*, *settype=None*)

Adds a set to the model

Parameters

name [string, optional] Name of the set

init [`Set`, optional] Initial value of the set

value [list, float, optional] Exact value of the set

settype [list, optional] Types of the set, a list consists of 'num' and 'str' values

Examples

```
>>> I = m.add_set(name='I')
>>> print(I._defn())
set I;
```

```
>>> J = m.add_set(name='J', settype=['str'])
>>> print(J._defn())
set <str> J;
```

```
>>> N = m.add_parameter(name='N', init=4)
>>> K = m.add_set(name='K', init=so.exp_range(1, N))
>>> print(K._defn())
set K = 1..N;
```

sasoptpy.Model.add_parameter

`Model.`**add_parameter**(*self*, **argv*, *name=None*, *init=None*, *value=None*, *p_type=None*)

Adds a parameter to the model

Parameters

argv [`Set`, optional] Key set of the parameter

name [string, optional] Name of the parameter

init [float or expression, optional] Initial value of the parameter

p_type [string, optional] Type of the parameter, 'num' for floats or 'str' for strings

Examples

```
>>> I = m.add_set(name='I')
>>> a = m.add_parameter(I, name='a', init=5)
>>> print(a._defn())
num a {I} init 5 ;
```

sasoptpy.Model.add_statement

Model.**add_statement**(*self*, *statement*, *after_solve=None*)

Adds a PROC OPTMODEL statement to the model

Parameters

statement [Expression or string] Statement object

Notes

- If the statement string includes 'print', then it is automatically placed after solve.
- The first parameter, *statement* could be a Statement object when internally used.

Examples

```
>>> I = m.add_set(name='I')
>>> x = m.add_variables(I, name='x', vartype=so.INT)
>>> a = m.add_parameter(I, name='a')
>>> c = m.add_constraints((x[i] <= 2 * a[i] for i in I), name='c')
>>> m.add_statement('print x;', after_solve=True)
>>> print(m.to_optmodel())
proc optmodel;
min m_obj = 0;
set I;
var x {I} integer >= 0;
num a {I};
con c {i_1 in I} : x[i_1] - 2.0 * a[i_1] <= 0;
solve;
print _var_.name _var_.lb _var_.ub _var_ _var_.rc;
print _con_.name _con_.body _con_.dual;
print x;
quit;
```

sasoptpy.Model.get_sets

Model.**get_sets**(*self*)

Returns a list of `Set` objects in the model

sasoptpy.Model.get_parameters

`Model.get_parameters(self)`

Returns a list of `Parameter` objects in the model

sasoptpy.Model.get_statements

`Model.get_statements(self)`

Returns a list of all abstract statements inside the model.

sasoptpy.Model.include

`Model.include(self, *argv)`

Adds existing variables and constraints to a model

Parameters

argv : Objects to be included in the model

Notes

- Valid argument types:
  - *Model*
  - *Variable*
  - *Constraint*
  - *VariableGroup*
  - *ConstraintGroup*
  - *Objective*
  - `Set`
  - `Parameter`
  - `ParameterGroup`
  - `Statement` and all subclasses
  - `ImplicitVar`
- Including a model causes all variables and constraints inside the original model to be included.

Examples

Adding an existing variable

```
>>> x = so.Variable(name='x', vartype=so.CONT)
>>> m.include(x)
```

Adding an existing constraint

```
>>> c1 = so.Constraint(x + y <= 5, name='c1')
>>> m.include(c1)
```

Adding an existing set of variables

```
>>> z = so.VariableGroup(3, 5, name='z', ub=10)
>>> m.include(z)
```

Adding an existing set of constraints

```
>>> c2 = so.ConstraintGroup((x + 2 * z[i, j] >= 2 for i in range(3)
                             for j in range(5)), name='c2')
>>> m.include(c2)
```

Adding an existing model (including all of its elements)

```
>>> new_model = so.Model(name='new_model')
>>> new_model.include(m)
```

Solver calls

`Model.solve`(self, **kwargs)	Solves the model by calling CAS or SAS optimization solvers
`Model.tune_parameters`(self, **kwargs)	Uses model tuner to find ideal parameters for given model
`Model.get_solution`(self[, vtype, solution, ...])	Returns the solution details associated with the primal or dual solution
`Model.get_variable_value`(self, var)	Returns the value of a variable.
`Model.get_objective_value`(self)	Returns the optimal objective value, if it exists
`Model.get_solution_summary`(self)	Returns the solution summary table to the user
`Model.get_problem_summary`(self)	Returns the problem summary table to the user
`Model.get_tuner_results`(self)	Returns the tuner responses for the model
`Model.print_solution`(self)	Prints the current values of the variables
`Model.clear_solution`(self)	Clears the cached solution of the model

sasoptpy.Model.solve

`Model.`**`solve`**(*self*, ***kwargs*)

Solves the model by calling CAS or SAS optimization solvers

Parameters

options [dict, optional] A dictionary solver options

submit [boolean, optional] Switch for calling the solver instantly

name [string, optional] Name of the table name

frame [boolean, optional] Switch for uploading problem as a MPS DataFrame format

drop [boolean, optional] Switch for dropping the MPS table after solve (only CAS)

replace [boolean, optional] Switch for replacing an existing MPS table (only CAS and MPS)

primalin [boolean, optional] Switch for using initial values (only MILP)

verbose [boolean, optional (experimental)] Switch for printing generated OPTMODEL code

Returns

solution [pandas.DataFrame] Solution of the optimization model

See also:

Model.solve_on_cas(), Model.solve_on_mva()

Notes

- This method is essentially a wrapper for two other methods.
- Some of the options listed under `options` argument may not be passed based on which CAS Action is being used.
- The `option` argument should be a dictionary, where keys are option names. For example, `m.solve(options={'maxtime': 600})` limits the solution time to 600 seconds.
- See *Solver Options* for a list of solver options.

Examples

```
>>> m.solve()
NOTE: Initialized model food_manufacture_1
NOTE: Converting model food_manufacture_1 to DataFrame
NOTE: Added action set 'optimization'.
...
NOTE: Optimal.
NOTE: Objective = 107842.59259.
NOTE: The Dual Simplex solve time is 0.01 seconds.
```

```
>>> m.solve(options={'maxtime': 600})
```

```
>>> m.solve(options={'algorithm': 'ipm'})
```

sasoptpy.Model.tune_parameters

`Model.`**`tune_parameters`**(*self*, ***kwargs*)

Uses model tuner to find ideal parameters for given model

Parameters

kwargs : Keyword arguments as defined in the optimization.tuner action Acceptable values are:

- milpParameters : Parameters for the solveMilp action, such as *maxTime*, *heuristics*, *feasTol*
- tunerParameters : Parameters for tuner itself, such as *maxConfigs*, *printLevel*, *logFreq*
- tuningParameters : List of parameters to be tuned, such as *cutStrategy*, *presolver*, *restarts*

Returns

tunerResults [swat.dataframe.SASDataFrame] Results of tuner as a table

See also:

Model.get_tuner_results()

Notes

- See SAS Optimization documentation for a full list of tunable parameters: https://go.documentation.sas.com/?docsetId=casactmopt&docsetTarget=cas-optimization-tuner.htm&docsetVersion=8.5&locale=en#PYTHON.cas-optimization-tuner-tunerparameters
- See full documentation at: https://go.documentation.sas.com/?docsetId=casactmopt&docsetTarget=casactmopt_optimization_details35.htm&docsetVersion=8.5&locale=en

Examples

```
>>> m = so.Model(name='model1')
>>> ...
>>> results = m.tune_parameters(tunerParameters={'maxConfigs': 10})
NOTE: Initialized model knapsack_with_tuner.
NOTE: Added action set 'optimization'.

```

sasoptpy.Model.get_solution

`Model.`**`get_solution`**(*self*, *vtype='Primal'*, *solution=None*, *pivot=False*)

Returns the solution details associated with the primal or dual solution

Parameters

vtype [string, optional] 'Primal' or 'Dual'

solution [integer, optional] Solution number to be returned (for MILP)

pivot [boolean, optional] Switch for returning multiple solutions in columns as a pivot table

Returns

solution [`pandas.DataFrame`] Primal or dual solution table returned from the CAS Action

Notes

- If `Model.solve()` method is used with `frame=True` option, MILP solver returns multiple solutions. You can obtain different results using `solution` parameter.

Examples

```
>>> m.solve()
>>> print(m.get_solution('Primal'))
             var   lb             ub  value  solution
0       x[clock]  0.0  1.797693e+308    0.0       1.0
1          x[pc]  0.0  1.797693e+308    5.0       1.0
2   x[headphone]  0.0  1.797693e+308    2.0       1.0

```

sasoptpy.Model.get_variable_value

`Model.`**`get_variable_value`**(*self*, *var*)

Returns the value of a variable.

Parameters

var [Variable or string] Variable reference

Notes

- It is possible to get a variable's value by using the *`Variable.get_value()`* method, if the variable is not abstract.
- This method is a wrapper around *`Variable.get_value()`* and an overlook function for model components

sasoptpy.Model.get_objective_value

`Model.`**`get_objective_value`**(*self*)

Returns the optimal objective value, if it exists

Returns

objective_value [float] Objective value at current solution

Notes

- This method should be used for getting the objective value after solve. Using `m.get_objective().get_value()` actually evaluates the expression using optimal variable values. This may not be available for nonlinear expressions.

Examples

```
>>> m.solve()
>>> print(m.get_objective_value())
42.0
```

sasoptpy.Model.get_solution_summary

`Model.get_solution_summary(self)`

Returns the solution summary table to the user

Returns

ss [`swat.dataframe.SASDataFrame`] Solution summary obtained after solve

Examples

```
>>> m.solve()
>>> soln = m.get_solution_summary()
>>> print(type(soln))
<class 'swat.dataframe.SASDataFrame'>
```

```
>>> print(soln)
Solution Summary
                              Value
Label
Solver                           LP
Algorithm              Dual Simplex
Objective Function              obj
Solution Status             Optimal
Objective Value                  10
Primal Infeasibility              0
Dual Infeasibility                0
Bound Infeasibility               0
Iterations                        2
Presolve Time                  0.00
Solution Time                  0.01
```

```
>>> print(soln.index)
Index(['Solver', 'Algorithm', 'Objective Function', 'Solution Status',
       'Objective Value', '', 'Primal Infeasibility',
       'Dual Infeasibility', 'Bound Infeasibility', '', 'Iterations',
       'Presolve Time', 'Solution Time'],
      dtype='object', name='Label')
```

```
>>> print(soln.loc['Solution Status', 'Value'])
Optimal
```

sasoptpy.Model.get_problem_summary

`Model.get_problem_summary(self)`

Returns the problem summary table to the user

Returns

ps [swat.dataframe.SASDataFrame] Problem summary obtained after *Model.solve()*

Examples

```
>>> m.solve()
>>> ps = m.get_problem_summary()
>>> print(type(ps))
<class 'swat.dataframe.SASDataFrame'>
```

```
>>> print(ps)
Problem Summary
                                Value
Label
Problem Name                   model1
Objective Sense          Maximization
Objective Function                obj
RHS                               RHS
Number of Variables                 2
Bounded Above                       0
Bounded Below                       2
Bounded Above and Below             0
Free                                0
Fixed                               0
Number of Constraints               2
LE (<=)                             1
EQ (=)                              0
GE (>=)                             1
Range                               0
Constraint Coefficients             4
```

```
>>> print(ps.index)
Index(['Problem Name', 'Objective Sense', 'Objective Function', 'RHS',
'', 'Number of Variables', 'Bounded Above', 'Bounded Below',
'Bounded Above and Below', 'Free', 'Fixed', '',
'Number of Constraints', 'LE (<=)', 'EQ (=)', 'GE (>=)', 'Range', '',
'Constraint Coefficients'],
dtype='object', name='Label')
```

```
>>> print(ps.loc['Number of Variables'])
Value               2
Name: Number of Variables, dtype: object
```

```
>>> print(ps.loc['Constraint Coefficients', 'Value'])
4
```

sasoptpy.Model.get_tuner_results

`Model.get_tuner_results(self)`
Returns the tuner responses for the model

Returns

tunerResults [dict] Returns tuner results as a dictionary. Its members are - Performance Information - Tuner Information - Tuner Summary - Tuner Results

See also:

Model.tune_parameters()

Examples

```
>>> m.tune_parameters(tunerParameters={'maxConfigs': 10})
>>> results = m.get_tuner_reults()
```

sasoptpy.Model.print_solution

`Model.print_solution(self)`
Prints the current values of the variables

See also:

Model.get_solution()

Notes

- This function may not work for abstract variables and nonlinear models.

Examples

```
>>> m.solve()
>>> m.print_solution()
x: 2.0
y: 0.0
```

sasoptpy.Model.clear_solution

`Model.clear_solution(self)`
Clears the cached solution of the model

Notes

- This method only cleans model's own parameters, not its components'

Export

`Model.to_mps`(self, **kwargs)	
`Model.to_optmodel`(self, **kwargs)	

sasoptpy.Model.to_mps

`Model.to_mps(self, **kwargs)`

sasoptpy.Model.to_optmodel

`Model.to_optmodel(self, **kwargs)`

Internal functions

`Model._is_linear`(self)	Checks if the model can be written as a linear model (in MPS format)

sasoptpy.Model._is_linear

`Model._is_linear(self)`

Checks if the model can be written as a linear model (in MPS format)

Returns

is_linear [boolean] True if model does not have any nonlinear components or abstract operations, False otherwise

Deprecated

Deprecated since version 1.0.0.

The following method(s) are deprecated and will be removed in future minor updates.

`Model.to_frame`(self, **kwargs)	

sasoptpy.Model.to_frame

Model.**to_frame**(*self*, ***kwargs*)

5.1.2 Expression

Constructor

Expression([exp, name])	Creates a mathematical expression to represent model components
Auxiliary(base[, prefix, suffix, operator, ...])	Represents an auxiliary expression, often as a symbolic attribute
Symbol(name)	Represents a symbolic string, to be evaluated on server-side

sasoptpy.Expression

class Expression(*exp=None*, *name=None*)

Bases: object

Creates a mathematical expression to represent model components

Parameters

exp [Expression, optional] An existing expression where arguments are being passed

name [string, optional] A local name for the expression

temp [boolean, optional] A boolean shows whether expression is temporary or permanent

Notes

- Two other classes (*Variable* and *Constraint*) are subclasses of this class.
- Expressions are created automatically after linear math operations with variables.
- An expression object can be called when defining constraints and other expressions.

Examples

```
>>> x = so.Variable(name='x')
>>> y = so.VariableGroup(3, name='y')
>>> e = so.Expression(exp=x + 3 * y[0] - 5 * y[1], name='exp1')
>>> print(e)
 -  5.0 * y[1]  +  3.0 * y[0]  +  x
>>> print(repr(e))
sasoptpy.Expression(exp =  -  5.0 * y[1]  +  3.0 * y[0]  +  x ,
                    name='exp1')
```

```
>>> sales = so.Variable(name='sales')
>>> material = so.Variable(name='material')
>>> profit = 5 * sales - 3 * material
```

(continues on next page)

(continued from previous page)

```
>>> print(profit)
 5.0 * sales  -  3.0 * material
>>> print(repr(profit))
sasoptpy.Expression(exp =  5.0 * sales  -  3.0 * material , name=None)
```

```
>>> import sasoptpy.abstract.math as sm
>>> f = sm.sin(x) + sm.min(y[1],1) ** 2
>>> print(type(f))
<class 'sasoptpy.core.Expression'>
>>> print(f)
sin(x) + (min(y[1] , 1)) ** (2)
```

sasoptpy.Auxiliary

class Auxiliary(*base*, *prefix=None*, *suffix=None*, *operator=None*, *value=None*)

Bases: `sasoptpy.core.expression.Expression`

Represents an auxiliary expression, often as a symbolic attribute

Parameters

base [*Expression*] Original owner of the auxiliary value

prefix [string, optional] Prefix of the expression

suffix [string, optional] Suffix of the expression

operator [string, optional] Wrapping operator

value [float, optional] Initial value of the symbolic object

Notes

- Auxiliary objects are for internal use

sasoptpy.Symbol

class Symbol(*name*)

Bases: `sasoptpy.core.expression.Expression`

Represents a symbolic string, to be evaluated on server-side

Parameters

name [string] String to be symbolized

Notes

- Symbol objects can be used for values that does not translate to a value on client-side, but have meaning on execution. For example, *_N_* is a SAS symbol, which can be used in OPTMODEL strings.

General methods

Expression.set_name(self[, name])	Sets the name of the expression
Expression.set_permanent(self)	Converts a temporary expression into a permanent one
Expression.set_temporary(self)	Converts expression into temporary to enable in-place operations
Expression.get_name(self)	Returns the name of the expression
Expression.get_value(self)	Calculates and returns the value of the linear expression
Expression.get_dual(self)	Returns the dual value if exists

sasoptpy.Expression.set_name

Expression.**set_name**(*self*, *name=None*)

Sets the name of the expression

Parameters

name [string] Name of the expression

Returns

name [string] Name of the expression after resolving conflicts

Examples

```
>>> x = so.Variable(name='x')
>>> e = x**2 + 2*x + 1
>>> e.set_name('expansion')
```

sasoptpy.Expression.set_permanent

Expression.**set_permanent**(*self*)

Converts a temporary expression into a permanent one

Parameters

name [string, optional] Name of the expression

Returns

name [string] Name of the expression in the namespace

sasoptpy.Expression.set_temporary

Expression.**set_temporary**(*self*)
Converts expression into temporary to enable in-place operations

sasoptpy.Expression.get_name

Expression.**get_name**(*self*)
Returns the name of the expression

Returns

name [string] Name of the expression

Examples

```
>>> m = so.Model()
>>> var1 = m.add_variables(name='x')
>>> print(var1.get_name())
x
```

sasoptpy.Expression.get_value

Expression.**get_value**(*self*)
Calculates and returns the value of the linear expression

Returns

v [float] Value of the expression

Examples

```
>>> sales = so.Variable(name='sales', init=10)
>>> material = so.Variable(name='material', init=3)
>>> profit = so.Expression(5 * sales - 3 * material)
>>> print(profit.get_value())
41
```

sasoptpy.Expression.get_dual

Expression.**get_dual**(*self*)
Returns the dual value if exists

Returns

dual [float] Dual value of the variable

Operations

`Expression.add`(self, other[, sign])	Combines two expressions and produces a new one
`Expression.copy`(self[, name])	Returns a copy of the `Expression` object
`Expression.mult`(self, other)	Multiplies the `Expression` with a scalar value
`Expression.get_member`(self, key)	Returns the requested member using the key
`Expression.get_member_dict`(self)	Returns an ordered dictionary of elements
`Expression.get_member_value`(self, key)	Returns coefficient of requested member
`Expression.get_constant`(self)	Returns the constant term in the expression
`Expression.set_member`(self, key, ref, val[, op])	Adds a new member or changes an existing member
`Expression.set_member_value`(self, key, value)	Changes the coefficient of the requested member
`Expression.add_to_member_value`(self, key, value)	Adds given value to the coefficient of the requested member
`Expression.mult_member_value`(self, key, value)	Multiplies coefficient of the requested member with given value
`Expression.copy_member`(self, key, exp)	Copies member of another expression
`Expression.delete_member`(self, key)	Deletes the requested member from the core dictionary

sasoptpy.Expression.add

`Expression.`**add**(*self*, *other*, *sign=1*)

Combines two expressions and produces a new one

Parameters

other [float or Expression] Second expression or constant value to be added

sign [int, optional] Sign of the addition, 1 or -1

Returns

r [Expression] Reference to the outcome of the operation

Notes

- Adding an expression is equivalent to calling this method: (x-y)+(3*x-2*y) and (x-y).add(3*x-2*y) result the same.

sasoptpy.Expression.copy

`Expression.`**copy**(*self*, *name=None*)

Returns a copy of the `Expression` object

Parameters

name [string, optional] Name for the copy

Returns

r [Expression] Copy of the object

Examples

```
>>> x = so.Variable(name='x')
>>> y = so.VariableGroup(1, name='y')
>>> e = so.Expression(7 * x - y[0], name='e')
>>> print(repr(e))
sasoptpy.Expression(exp =  -  y[0]  +  7.0 * x , name='e')
>>> f = e.copy(name='f')
>>> print(repr(f))
sasoptpy.Expression(exp =  -  y[0]  +  7.0 * x , name='f')
```

sasoptpy.Expression.mult

`Expression.mult(self, other)`

Multiplies the `Expression` with a scalar value

Parameters

other [Expression or int] Second expression to be multiplied

Returns

r [Expression] A new `Expression` that represents the multiplication

Notes

- This method is mainly for internal use.
- Multiplying an expression is equivalent to calling this method: 3*(x-y) and (x-y).mult(3) are interchangeable.

sasoptpy.Expression.get_member

`Expression.get_member(self, key)`

Returns the requested member using the key

Parameters

key [string] Identifier of the member, name for single objects

Returns

member [dict] A dictionary of coefficient, operator, and reference of member

sasoptpy.Expression.get_member_dict

`Expression.get_member_dict(self)`

Returns an ordered dictionary of elements

sasoptpy.Expression.get_member_value

Expression.**get_member_value**(*self*, *key*)

Returns coefficient of requested member

Parameters

key [string] Identifier of the member

Returns

value [float] Coefficient value of the requested member

sasoptpy.Expression.get_constant

Expression.**get_constant**(*self*)

Returns the constant term in the expression

Examples

```
>>> x = so.Variable(name='x')
>>> e = 2 * x + 5
>>> print(e.get_constant())
5
```

sasoptpy.Expression.set_member

Expression.**set_member**(*self*, *key*, *ref*, *val*, *op=None*)

Adds a new member or changes an existing member

Parameters

key [string] Identifier of the member

ref [Object] A reference to the new member

val [float] Initial coefficient of the element

op [string, optional] Operator, if member consists of multiple children

sasoptpy.Expression.set_member_value

Expression.**set_member_value**(*self*, *key*, *value*)

Changes the coefficient of the requested member

Parameters

key [string] Identifier of the member

value [float] New coefficient value of the member

sasoptpy.Expression.add_to_member_value

`Expression.add_to_member_value(self, key, value)`

Adds given value to the coefficient of the requested member

Parameters

key [string] Identifier of the member

value [float] Value to be added

sasoptpy.Expression.mult_member_value

`Expression.mult_member_value(self, key, value)`

Multiplies coefficient of the requested member with given value

Parameters

key [string] Identifier of the member

value [float] Value to be multiplied with

sasoptpy.Expression.copy_member

`Expression.copy_member(self, key, exp)`

Copies member of another expression

Parameters

key [string] Identifier of the member

exp [*Expression*] Other expression to be copied from

sasoptpy.Expression.delete_member

`Expression.delete_member(self, key)`

Deletes the requested member from the core dictionary

Class methods

Expression.to_expression(obj)

sasoptpy.Expression.to_expression

classmethod Expression.**to_expression**(*obj*)

Private Methods

Expression._expr(self)	Generates the OPTMODEL compatible string representation of the object.
Expression._is_linear(self)	Checks if the expression is composed of linear components
Expression._relational(self, other, direction_)	Creates a logical relation between *Expression* objects
Expression.__repr__(self)	Returns a string representation of the object.
Expression.__str__(self)	Generates a representation string that is Python compatible

sasoptpy.Expression._expr

Expression.**_expr**(*self*)

Generates the OPTMODEL compatible string representation of the object.

Examples

```
>>> x = so.Variable(name='x')
>>> y = so.Variable(name='y')
>>> f = x + y ** 2
>>> print(f)
x + (y) ** (2)
>>> print(f._expr())
x + (y) ^ (2)
```

sasoptpy.Expression._is_linear

Expression.**_is_linear**(*self*)

Checks if the expression is composed of linear components

Returns

is_linear [boolean] True if the expression is linear, False otherwise

Examples

```
>>> x = so.Variable()
>>> e = x*x
>>> print(e.is_linear())
False
```

```
>>> f = x*x + x*x - 2*x*x + 5
>>> print(f.is_linear())
True
```

sasoptpy.Expression._relational

Expression.**_relational**(*self*, *other*, *direction_*)

Creates a logical relation between `Expression` objects

Parameters

other [Expression] Expression on the other side of the relation wrt self

direction_ [string] Direction of the logical relation, either 'E', 'L', or 'G'

Returns

generated_constraint [Constraint] Constraint generated as a result of linear relation

sasoptpy.Expression.__repr__

Expression.**__repr__**(*self*)

Returns a string representation of the object.

Examples

```
>>> x = so.Variable(name='x')
>>> y = so.Variable(name='y')
>>> f = x + y ** 2
>>> print(repr(f))
sasoptpy.Expression(exp = x + (y) ** (2), name=None)
```

sasoptpy.Expression.__str__

Expression.**__str__**(*self*)

Generates a representation string that is Python compatible

Examples

```
>>> f = x + y ** 2
>>> print(str(f))
x + (y) ** (2)
```

5.1.3 Variable

Constructor

Objective(**kwargs)	Objective represents expressions with sense and used as target value in optimization

sasoptpy.Objective

class Objective(***kwargs*)

Bases: `sasoptpy.core.expression.Expression`

Objective represents expressions with sense and used as target value in optimization

Parameters

exp [*Expression*] Objective as an expression

name [string] Unique name of the expression

sense [string, optional] Direction of the objective, sasoptpy.MIN (default) or sasoptpy.MAX

Examples

```
>>> m = so.Model(name='test_objective')
>>> x = m.add_variable(name='x')
>>> obj = m.set_objective(2 * x - x ** 3, sense=so.MIN, name='new_obj')
>>> str(m.get_objective())
2 * x - (x) ** (3)
>>> type(obj)
sasoptpy.Objective
```

Methods

Objective.set_sense(self, sense)	Sets the objective sense (direction)
Objective.get_sense(self)	Returns the objective sense (direction)

sasoptpy.Objective.set_sense

`Objective.set_sense(self, sense)`

Sets the objective sense (direction)

Parameters

sense [string] sasoptpy.MIN or sasoptpy.MAX

sasoptpy.Objective.get_sense

`Objective.get_sense(self)`

Returns the objective sense (direction)

5.1.4 Variable

Constructor

`Variable`(**kwargs)	Creates an optimization variable to be used inside models

sasoptpy.Variable

class Variable(***kwargs*)

Bases: `sasoptpy.core.expression.Expression`

Creates an optimization variable to be used inside models

Parameters

name [string] Name of the variable

vartype [string, optional] Type of the variable, default is continuous

lb [float, optional] Lower bound of the variable, default is -inf

ub [float, optional] Upper bound of the variable, default is inf

init [float, optional] Initial value of the variable

abstract [boolean, optional] Indicator of whether the variable is abstract or not

shadow [boolean, optional] Indicator of whether the variable is shadow or not Used for internal purposes

See also:

`sasoptpy.Model.add_variable()`

Examples

```
>>> x = so.Variable(name='x', lb=0, ub=20, vartype=so.CONT)
>>> print(repr(x))
sasoptpy.Variable(name='x', lb=0, ub=20, vartype='CONT')
```

```
>>> y = so.Variable(name='y', init=1, vartype=so.INT)
>>> print(repr(y))
sasoptpy.Variable(name='y', lb=0, ub=inf, init=1, vartype='INT')
```

Attributes

lb Lower bound of the variable

ub Upper bound of the variable

Attributes

Variable.lb	Lower bound of the variable
Variable.ub	Upper bound of the variable

sasoptpy.Variable.lb

property Variable.**lb**
Lower bound of the variable

sasoptpy.Variable.ub

property Variable.**ub**
Upper bound of the variable

Methods

Variable.set_bounds(self, *[, lb, ub])	Changes bounds on a variable
Variable.set_init(self[, init])	Changes initial value of a variable
Variable.get_type(self)	Returns the type of variable, valid values are:
Variable.get_attributes(self)	Returns an OrderedDict of main attributes

sasoptpy.Variable.set_bounds

Variable.**set_bounds**(*self*, *, *lb=None*, *ub=None*)
Changes bounds on a variable

Parameters

lb [float or *Expression*] Lower bound of the variable

ub [float or *Expression*] Upper bound of the variable

Examples

```
>>> x = so.Variable(name='x', lb=0, ub=20)
>>> print(repr(x))
sasoptpy.Variable(name='x', lb=0, ub=20, vartype='CONT')
>>> x.set_bounds(lb=5, ub=15)
>>> print(repr(x))
sasoptpy.Variable(name='x', lb=5, ub=15, vartype='CONT')
```

sasoptpy.Variable.set_init

Variable.**set_init**(*self*, *init=None*)

Changes initial value of a variable

Parameters

init [float or None] Initial value of the variable

Examples

```
>>> x = so.Variable(name='x')
>>> x.set_init(5)
```

```
>>> y = so.Variable(name='y', init=3)
>>> y.set_init()
```

sasoptpy.Variable.get_type

Variable.**get_type**(*self*)

Returns the type of variable, valid values are:

- sasoptpy.CONT
- sasoptpy.INT
- sasoptpy.BIN

sasoptpy.Variable.get_attributes

Variable.**get_attributes**(*self*)

Returns an OrderedDict of main attributes

Returns

attributes [dict] OrderedDict consists of *init*, *lb*, and *ub* attributes

Inherited Methods

Variable.copy(self[, name])	Returns a copy of the *Expression* object
Variable.get_dual(self)	Returns the dual value if exists
Variable.get_name(self)	Returns the name of the expression
Variable.get_value(self)	Returns value of a variable

sasoptpy.Variable.copy

Variable.**copy**(*self*, *name=None*)

Returns a copy of the *Expression* object

Parameters

name [string, optional] Name for the copy

Returns

r [Expression] Copy of the object

Examples

```
>>> x = so.Variable(name='x')
>>> y = so.VariableGroup(1, name='y')
>>> e = so.Expression(7 * x - y[0], name='e')
>>> print(repr(e))
sasoptpy.Expression(exp =  -  y[0]  +  7.0 * x , name='e')
>>> f = e.copy(name='f')
>>> print(repr(f))
sasoptpy.Expression(exp =  -  y[0]  +  7.0 * x , name='f')
```

sasoptpy.Variable.get_dual

Variable.**get_dual**(*self*)

Returns the dual value if exists

Returns

dual [float] Dual value of the variable

sasoptpy.Variable.get_name

Variable.**get_name**(*self*)

Returns the name of the expression

Returns

name [string] Name of the expression

Examples

```
>>> m = so.Model()
>>> var1 = m.add_variables(name='x')
>>> print(var1.get_name())
x
```

sasoptpy.Variable.get_value

`Variable.get_value(self)`
Returns value of a variable

5.1.5 Variable Group

Constructor

`VariableGroup`(**kwargs)	Creates a group of `Variable` objects

sasoptpy.VariableGroup

class VariableGroup(***kwargs*)
Bases: `sasoptpy.core.group.Group`

Creates a group of `Variable` objects

Parameters

argv [list, dict, int, `pandas.Index`] Loop index for variable group

name [string, optional] Name (prefix) of the variables

vartype [string, optional] Type of variables, *BIN*, *INT*, or *CONT*

lb [list, dict, `pandas.Series`, optional] Lower bounds of variables

ub [list, dict, `pandas.Series`, optional] Upper bounds of variables

init [float, optional] Initial values of variables

See also:

`sasoptpy.Model.add_variables()`

`sasoptpy.Model.include()`

Notes

- When working with a single model, use the *sasoptpy.Model.add_variables()* method.
- If a variable group object is created, it can be added to a model using the *sasoptpy.Model.include()* method.
- An individual variable inside the group can be accessed using indices.

```
>>> z = so.VariableGroup(2, ['a', 'b', 'c'], name='z', lb=0, ub=10)
>>> print(repr(z[0, 'a']))
sasoptpy.Variable(name='z_0_a', lb=0, ub=10, vartype='CONT')
```

Examples

```
>>> PERIODS = ['Period1', 'Period2', 'Period3']
>>> production = so.VariableGroup(PERIODS, vartype=so.INT,
                                  name='production', lb=10)
>>> print(production)
Variable Group (production) [
  [Period1: production['Period1']]
  [Period2: production['Period2']]
  [Period3: production['Period3']]
]
```

```
>>> x = so.VariableGroup(4, vartype=so.BIN, name='x')
>>> print(x)
Variable Group (x) [
  [0: x[0]]
  [1: x[1]]
  [2: x[2]]
  [3: x[3]]
]
```

```
>>> z = so.VariableGroup(2, ['a', 'b', 'c'], name='z')
>>> print(z)
Variable Group (z) [
  [(0, 'a'): z[0, 'a']]
  [(0, 'b'): z[0, 'b']]
  [(0, 'c'): z[0, 'c']]
  [(1, 'a'): z[1, 'a']]
  [(1, 'b'): z[1, 'b']]
  [(1, 'c'): z[1, 'c']]
]
>>> print(repr(z))
sasoptpy.VariableGroup([0, 1], ['a', 'b', 'c'], name='z')
```

Methods

VariableGroup.get_name(self)	Returns the name of the variable group
VariableGroup.get_attributes(self)	Returns an OrderedDict of main attributes
VariableGroup.get_type(self)	Returns the type of variable, valid values are:
VariableGroup.get_members(self)	Returns a dictionary of members
VariableGroup.set_bounds(self[, lb, ub, members])	Sets / updates bounds for the given variable
VariableGroup.set_init(self, init)	Sets / updates initial value for the given variable
VariableGroup.mult(self, vector)	Quick multiplication method for the variable groups
VariableGroup.sum(self, *argv)	Quick sum method for the variable groups

sasoptpy.VariableGroup.get_name

VariableGroup.**get_name**(*self*)

Returns the name of the variable group

Returns

name [string] Name of the variable group

Examples

```
>>> m = so.Model(name='m')
>>> var1 = m.add_variables(4, name='x')
>>> print(var1.get_name())
x
```

sasoptpy.VariableGroup.get_attributes

VariableGroup.**get_attributes**(*self*)

Returns an OrderedDict of main attributes

Returns

attributes [dict] OrderedDict consists of *init*, *lb*, and *ub* attributes

sasoptpy.VariableGroup.get_type

VariableGroup.**get_type**(*self*)

Returns the type of variable, valid values are:

- sasoptpy.CONT
- sasoptpy.INT
- sasoptpy.BIN

sasoptpy.VariableGroup.get_members

`VariableGroup.get_members(self)`
Returns a dictionary of members

sasoptpy.VariableGroup.set_bounds

`VariableGroup.set_bounds(self, lb=None, ub=None, members=True)`
Sets / updates bounds for the given variable

Parameters

lb [float, `pandas.Series`, optional] Lower bound

ub [float, `pandas.Series`, optional] Upper bound

Examples

```
>>> z = so.VariableGroup(2, ['a', 'b', 'c'], name='z', lb=0, ub=10)
>>> print(repr(z[0, 'a']))
sasoptpy.Variable(name='z_0_a', lb=0, ub=10, vartype='CONT')
>>> z.set_bounds(lb=3, ub=5)
>>> print(repr(z[0, 'a']))
sasoptpy.Variable(name='z_0_a', lb=3, ub=5, vartype='CONT')
```

```
>>> u = so.VariableGroup(['a', 'b', 'c', 'd'], name='u')
>>> lb_vals = pd.Series([1, 4, 0, -1], index=['a', 'b', 'c', 'd'])
>>> u.set_bounds(lb=lb_vals)
>>> print(repr(u['b']))
sasoptpy.Variable(name='u_b', lb=4, ub=inf, vartype='CONT')
```

sasoptpy.VariableGroup.set_init

`VariableGroup.set_init(self, init)`
Sets / updates initial value for the given variable

Parameters

init [float, list, dict, `pandas.Series`] Initial value of the variables

Examples

```
>>> m = so.Model(name='m')
>>> y = m.add_variables(3, name='y')
>>> print(y._defn())
var y {{0,1,2}};
>>> y.set_init(5)
>>> print(y._defn())
var y {{0,1,2}} init 5;
```

sasoptpy.VariableGroup.mult

`VariableGroup.mult(self, vector)`
Quick multiplication method for the variable groups

Parameters

vector [list, dictionary, `pandas.Series`, or `pandas.DataFrame`] Vector to be multiplied with the variable group

Returns

r [Expression] An expression that is the product of the variable group with the given vector

Examples

Multiplying with a list

```
>>> x = so.VariableGroup(4, vartype=so.BIN, name='x')
>>> e1 = x.mult([1, 5, 6, 10])
>>> print(e1)
 10.0 * x[3]  +  6.0 * x[2]  +  x[0]  +  5.0 * x[1]
```

Multiplying with a dictionary

```
>>> y = so.VariableGroup([0, 1], ['a', 'b'], name='y', lb=0, ub=10)
>>> dvals = {(0, 'a'): 1, (0, 'b'): 2, (1, 'a'): -1, (1, 'b'): 5}
>>> e2 = y.mult(dvals)
>>> print(e2)
 2.0 * y[0, 'b']  -  y[1, 'a']  +  y[0, 'a']  +  5.0 * y[1, 'b']
```

Multiplying with a pandas.Series object

```
>>> u = so.VariableGroup(['a', 'b', 'c', 'd'], name='u')
>>> ps = pd.Series([0.1, 1.5, -0.2, 0.3], index=['a', 'b', 'c', 'd'])
>>> e3 = u.mult(ps)
>>> print(e3)
 1.5 * u['b']  +  0.1 * u['a']  -  0.2 * u['c']  +  0.3 * u['d']
```

Multiplying with a pandas.DataFrame object

```
>>> data = np.random.rand(3, 3)
>>> df = pd.DataFrame(data, columns=['a', 'b', 'c'])
>>> print(df)
NOTE: Initialized model model1
          a         b         c
0  0.966524  0.237081  0.944630
1  0.821356  0.074753  0.345596
2  0.065229  0.037212  0.136644
>>> y = m.add_variables(3, ['a', 'b', 'c'], name='y')
>>> e = y.mult(df)
>>> print(e)
0.9665237354418064 * y[0, 'a']  +  0.23708064143289442 * y[0, 'b']  +
0.944629500537536 * y[0, 'c']  +  0.8213562592159828 * y[1, 'a']  +
0.07475256894157478 * y[1, 'b']  +  0.3455957019116668 * y[1, 'c']  +
0.06522945752546017 * y[2, 'a']  +  0.03721153533250843 * y[2, 'b']  +
0.13664422498043194 * y[2, 'c']
```

sasoptpy.VariableGroup.sum

`VariableGroup.sum(self, *argv)`
Quick sum method for the variable groups

Parameters

argv [Arguments] List of indices for the sum

Returns

r [Expression] Expression that represents the sum of all variables in the group

Examples

```
>>> z = so.VariableGroup(2, ['a', 'b', 'c'], name='z', lb=0, ub=10)
>>> e1 = z.sum('*', '*')
>>> print(e1)
z[1, 'c']  +  z[1, 'a']  +  z[1, 'b']  +  z[0, 'a']  +  z[0, 'b']  +
z[0, 'c']
>>> e2 = z.sum('*', 'a')
>>> print(e2)
 z[1, 'a']  +  z[0, 'a']
>>> e3 = z.sum('*', ['a', 'b'])
>>> print(e3)
 z[1, 'a']  +  z[0, 'b']  +  z[1, 'b']  +  z[0, 'a']
```

5.1.6 Constraint

Constructor

Constraint(**kwargs)	Creates a linear or quadratic constraint for optimization models

sasoptpy.Constraint

class Constraint(**kwargs*)
Bases: `sasoptpy.core.expression.Expression`

Creates a linear or quadratic constraint for optimization models

Constraints should be created by adding logical relations to *Expression* objects.

Parameters

exp [Expression] A logical expression that forms the constraint

direction [string] Direction of the logical expression, 'E' (=), 'L' (<=) or 'G' (>=)

name [string, optional] Name of the constraint object

crange [float, optional] Range for ranged constraints

See also:

sasoptpy.Model.add_constraint()

Notes

- A constraint can be generated in multiple ways:
  1. Using the `sasoptpy.Model.add_constraint()` method

     ```
     >>> m = so.Model(name='m')
     >>> c1 = m.add_constraint(3 * x - 5 * y <= 10, name='c1')
     >>> print(repr(c1))
     sasoptpy.Constraint( - 5.0 * y + 3.0 * x <= 10, name='c1')
     ```

  2. Using the constructor

     ```
     >>> c1 = sasoptpy.Constraint(3 * x - 5 * y <= 10, name='c1')
     >>> print(repr(c1))
     sasoptpy.Constraint( - 5.0 * y + 3.0 * x <= 10, name='c1')
     ```

- The same constraint can be included into other models using the `Model.include()` method.

Examples

```
>>> x = so.Variable(name='x')
>>> y = so.Variable(name='y')
>>> c1 = so.Constraint( 3 * x - 5 * y <= 10, name='c1')
>>> print(repr(c1))
sasoptpy.Constraint( - 5.0 * y + 3.0 * x <= 10, name='c1')
```

```
>>> c2 = so.Constraint( - x + 2 * y - 5, direction='L', name='c2')
sasoptpy.Constraint( - x + 2.0 * y <= 5, name='c2')
```

Methods

`Constraint.get_value`(self[, rhs])	Returns the current value of the constraint
`Constraint.set_block`(self, block_number)	Sets the decomposition block number for a constraint
`Constraint.set_direction`(self, direction)	Changes the direction of a constraint
`Constraint.set_rhs`(self, value)	Changes the RHS of a constraint
`Constraint.update_var_coef`(self, var, value)	Updates the coefficient of a variable inside the constraint

sasoptpy.Constraint.get_value

`Constraint.get_value`(*self*, *rhs=False*)

Returns the current value of the constraint

Parameters

rhs [boolean, optional] Whether constant values (RHS) will be included in the value or not. Default is false

Examples

```
>>> x = so.Variable(name='x', init=2)
>>> c = so.Constraint(x ** 2 + 2 * x <= 15, name='c')
>>> print(c.get_value())
8
>>> print(c.get_value(rhs=True))
-7
```

sasoptpy.Constraint.set_block

`Constraint.set_block(self, block_number)`

Sets the decomposition block number for a constraint

Parameters

block_number [int] Block number of the constraint

Examples

```
>>> c1 = m.add_constraints((x + 2 * y[i] <= 5 for i in NODES),
                           name='c1')
>>> for i in NODES:
      c1[i].set_block(i)
```

sasoptpy.Constraint.set_direction

`Constraint.set_direction(self, direction)`

Changes the direction of a constraint

Parameters

direction [string] Direction of the constraint, 'E', 'L', or 'G' for equal to, less than or equal to, and greater than or equal to, respectively

Examples

```
>>> c1 = so.Constraint(exp=3 * x - 5 * y <= 10, name='c1')
>>> print(repr(c1))
sasoptpy.Constraint( 3.0 * x  -  5.0 * y  <=  10, name='c1')
>>> c1.set_direction('G')
>>> print(repr(c1))
sasoptpy.Constraint( 3.0 * x  -  5.0 * y  >=  10, name='c1')
```

sasoptpy.Constraint.set_rhs

`Constraint.set_rhs(self, value)`
Changes the RHS of a constraint

Parameters

value [float] New RHS value for the constraint

Examples

```
>>> x = m.add_variable(name='x')
>>> y = m.add_variable(name='y')
>>> c = m.add_constraint(x + 3*y <= 10, name='con_1')
>>> print(c)
x  +  3.0 * y  <=  10
>>> c.set_rhs(5)
>>> print(c)
x  +  3.0 * y  <=  5
```

sasoptpy.Constraint.update_var_coef

`Constraint.update_var_coef(self, var, value)`
Updates the coefficient of a variable inside the constraint

Parameters

var [Variable] Variable to be updated

value [float] Coefficient of the variable in the constraint

See also:

`sasoptpy.Model.set_coef()`

Examples

```
>>> c1 = so.Constraint(exp=3 * x - 5 * y <= 10, name='c1')
>>> print(repr(c1))
sasoptpy.Constraint( -  5.0 * y  +  3.0 * x  <=  10, name='c1')
>>> c1.update_var_coef(x, -1)
>>> print(repr(c1))
sasoptpy.Constraint( -  5.0 * y  -  x  <=  10, name='c1')
```

5.1.7 Constraint Group

Constructor

ConstraintGroup(**kwargs)	Creates a group of Constraint objects

sasoptpy.ConstraintGroup

class ConstraintGroup(***kwargs*)

Bases: sasoptpy.core.group.Group

Creates a group of Constraint objects

Parameters

argv [Generator-type object] A Python generator that includes Expression objects

name [string, optional] Name (prefix) of the constraints

See also:

sasoptpy.Model.add_constraints()

sasoptpy.Model.include()

Notes

Use sasoptpy.Model.add_constraints() when working with a single model.

Examples

```
>>> var_ind = ['a', 'b', 'c', 'd']
>>> u = so.VariableGroup(var_ind, name='u')
>>> t = so.Variable(name='t')
>>> cg = so.ConstraintGroup((u[i] + 2 * t <= 5 for i in var_ind), name='cg')
>>> print(cg)
Constraint Group (cg) [
  [a:  2.0 * t  +  u['a']  <=  5]
  [b:  u['b']  +  2.0 * t  <=  5]
  [c:  2.0 * t  +  u['c']  <=  5]
  [d:  2.0 * t  +  u['d']  <=  5]
]
```

```
>>> z = so.VariableGroup(2, ['a', 'b', 'c'], name='z', lb=0, ub=10)
>>> cg2 = so.ConstraintGroup((2 * z[i, j] + 3 * z[i-1, j] >= 2 for i in
                              [1] for j in ['a', 'b', 'c']), name='cg2')
>>> print(cg2)
Constraint Group (cg2) [
  [(1, 'a'):  3.0 * z[0, 'a']  +  2.0 * z[1, 'a']  >=  2]
  [(1, 'b'):  2.0 * z[1, 'b']  +  3.0 * z[0, 'b']  >=  2]
  [(1, 'c'):  2.0 * z[1, 'c']  +  3.0 * z[0, 'c']  >=  2]
]
```

Methods

ConstraintGroup.get_name(self)	Returns the name of the constraint group
ConstraintGroup.get_all_keys(self)	Returns a list of all keys (indices) in the group
ConstraintGroup.get_expressions(self[, rhs])	Returns constraints as a list of expressions
ConstraintGroup.get_members(self)	Returns a dictionary of members

sasoptpy.ConstraintGroup.get_name

ConstraintGroup.**get_name**(*self*)

Returns the name of the constraint group

Returns

name [string] Name of the constraint group

Examples

```
>>> m = so.Model(name='m')
>>> x = m.add_variable(name='x')
>>> indices = ['a', 'b', 'c']
>>> y = m.add_variables(indices, name='y')
>>> c1 = m.add_constraints((x + y[i] <= 4 for i in indices),
                           name='con1')
>>> print(c1.get_name())
con1
```

sasoptpy.ConstraintGroup.get_all_keys

ConstraintGroup.**get_all_keys**(*self*)

Returns a list of all keys (indices) in the group

sasoptpy.ConstraintGroup.get_expressions

ConstraintGroup.**get_expressions**(*self*, *rhs=False*)

Returns constraints as a list of expressions

Parameters

rhs [boolean, optional] Whether to pass the constant part (rhs) of the constraint or not

Returns

df [pandas.DataFrame] Returns a DataFrame consisting of constraints as expressions

Examples

```
>>> m = so.Model(name='m')
>>> var_ind = ['a', 'b', 'c', 'd']
>>> u = m.add_variables(var_ind, name='u')
>>> t = m.add_variable(name='t')
>>> cg = so.ConstraintGroup((u[i] + 2 * t <= 5 for i in var_ind),
                            name='cg')
>>> ce = cg.get_expressions()
>>> print(ce)
              cg
a  u[a] + 2 * t
b  u[b] + 2 * t
c  u[c] + 2 * t
d  u[d] + 2 * t
>>> ce_rhs = cg.get_expressions(rhs=True)
>>> print(ce_rhs)
                  cg
a  u[a] + 2 * t - 5
b  u[b] + 2 * t - 5
c  u[c] + 2 * t - 5
d  u[d] + 2 * t - 5
```

sasoptpy.ConstraintGroup.get_members

ConstraintGroup.**get_members**(*self*)

Returns a dictionary of members

5.1.8 Workspace

Constructor

Workspace(name[, session])	Workspace represents an OPTMODEL block that allows multiple solves

sasoptpy.Workspace

class Workspace(*name*, *session=None*)

Bases: object

Workspace represents an OPTMODEL block that allows multiple solves

Parameters

name [string] Name of the workspace

session [saspy.SASsession or swat.cas.connection.CAS, optional] Session to be submitted

Methods

`Workspace.get_elements`(self)	Returns a list of elements in the Workspace
`Workspace.set_active_model`(self, model)	Marks given model as active, to be used in solve statements
`Workspace.append`(self, element)	Appends a new element (operation or statement) to the Workspace
`Workspace.submit`(self, **kwargs)	Submits the Workspace as an OPTMODEL block and returns solutions
`Workspace.parse_solve_responses`(self)	Grabs the solutions to all solve statements
`Workspace.parse_print_responses`(self)	Grabs responses to all print statements
`Workspace.get_variable`(self, name)	Obtains the value of a given variable name
`Workspace.set_variable_value`(self, name, value)	Sets variable value
`Workspace.to_optmodel`(self)	Returns equivalent OPTMODEL code of given workspace

sasoptpy.Workspace.get_elements

`Workspace.`**`get_elements`**`(`*self*`)`

Returns a list of elements in the Workspace

sasoptpy.Workspace.set_active_model

`Workspace.`**`set_active_model`**`(`*self, model*`)`

Marks given model as active, to be used in solve statements

Parameters

model [`Model`] Model to be activated

sasoptpy.Workspace.append

`Workspace.`**`append`**`(`*self, element*`)`

Appends a new element (operation or statement) to the Workspace

Parameters

element [`sasoptpy.abstract.Statement`] Any statement that can be appended

sasoptpy.Workspace.submit

`Workspace.`**`submit`**`(`*self, **kwargs*`)`

Submits the Workspace as an OPTMODEL block and returns solutions

sasoptpy.Workspace.parse_solve_responses

`Workspace.parse_solve_responses(self)`
Grabs the solutions to all solve statements

sasoptpy.Workspace.parse_print_responses

`Workspace.parse_print_responses(self)`
Grabs responses to all print statements

sasoptpy.Workspace.get_variable

`Workspace.get_variable(self, name)`
Obtains the value of a given variable name

Parameters

name [string] Name of the variable

sasoptpy.Workspace.set_variable_value

`Workspace.set_variable_value(self, name, value)`
Sets variable value

Parameters

name [string] Name of the variable

value [float] New value of the variable

sasoptpy.Workspace.to_optmodel

`Workspace.to_optmodel(self)`
Returns equivalent OPTMODEL code of given workspace

Returns

optmodel [string] Generated OPTMODEL code of the workspace object

5.2 Abstract

5.2.1 Abstract

Main classes

Parameter(**kwargs)	
ParameterGroup(**kwargs)	
Set(**kwargs)	Creates an index set to be represented inside PROC OPTMODEL

Continued on next page

Table 26 – continued from previous page

SetIterator(initset[, name, datatype])	Creates an iterator object for a given Set
SetIteratorGroup(initset[, datatype, names])	
Statement()	

sasoptpy.abstract.Parameter

class Parameter(***kwargs*)

Bases: `sasoptpy.core.expression.Expression`

sasoptpy.abstract.ParameterGroup

class ParameterGroup(***kwargs*)

Bases: `object`

sasoptpy.abstract.Set

class Set(***kwargs*)

Bases: `object`

Creates an index set to be represented inside PROC OPTMODEL

Parameters

name [string] Name of the parameter

init [Expression, optional] Initial value expression of the parameter

settype [list, optional] List of types for the set, consisting of 'num' and 'str' values

Examples

```
>>> I = so.Set('I')
>>> print(I._defn())
set I;
```

```
>>> J = so.Set('J', settype=['num', 'str'])
>>> print(J._defn())
set <num, str> J;
```

```
>>> N = so.Parameter(name='N', init=5)
>>> K = so.Set('K', init=so.exp_range(1,N))
>>> print(K._defn())
set K = 1..N;
```

sasoptpy.abstract.SetIterator

class SetIterator(*initset*, *name=None*, *datatype=None*)
Bases: `sasoptpy.core.expression.Expression`

Creates an iterator object for a given Set

Parameters

initset [Set] Set to be iterated on

name [string, optional] Name of the iterator

datatype [string, optional] Type of the iterator

Notes

- SetIterator objects are automatically created when looping over a `Set`.
- This class is mainly intended for internal use.
- The `group` parameter consists of following keys
  - **order** : int Order of the parameter inside the group
  - **outof** : int Total number of indices inside the group
  - **id** : int ID number assigned to group by Python

sasoptpy.abstract.SetIteratorGroup

class SetIteratorGroup(*initset*, *datatype=None*, *names=None*)
Bases: `collections.OrderedDict`, `sasoptpy.core.expression.Expression`

sasoptpy.abstract.Statement

class Statement
Bases: `abc.ABC`

Statements

`Assignment`(identifier, expression[, keyword])	
`CoForLoopStatement`(*args)	
`CreateDataStatement`(table, index[, columns])	
`DropStatement`(**kwargs)	
`ForLoopStatement`(*args)	
`IfElseStatement`(logic_expression, if_statement)	
`LiteralStatement`(**kwargs)	
`ObjectiveStatement`(expression, **kwargs)	
`ReadDataStatement`(table, index[, columns])	
`SolveStatement`(*args, **kwargs)	
`FixStatement`(*elements)	
`UnfixStatement`(*elements)	

Continued on next page

Table 27 – continued from previous page

PrintStatement(*args)	

sasoptpy.abstract.statement.Assignment

class Assignment(*identifier, expression, keyword=None*)

Bases: `sasoptpy.abstract.statement.statement_base.Statement`

__init__(*self, identifier, expression, keyword=None*)

Initialize self. See help(type(self)) for accurate signature.

Methods

__init__(self, identifier, expression[, keyword])	Initialize self.
append(self, *args, **kwargs)	
fix_value(obj, value)	
get_response(self)	
is_internal(self)	
set_bounds(var, **kwargs)	
set_internal(self, value)	
set_response(self, response)	
set_value(obj, value)	

sasoptpy.abstract.statement.CoForLoopStatement

class CoForLoopStatement(**args*)

Bases: `sasoptpy.abstract.statement.for_loop.ForLoopStatement`

__init__(*self, *args*)

Initialize self. See help(type(self)) for accurate signature.

Methods

__init__(self, *args)	Initialize self.
append(self, element)	
cofor_loop(*args)	
for_loop(*args)	
get_response(self)	
is_internal(self)	
set_internal(self, value)	
set_response(self, response)	

sasoptpy.abstract.statement.CreateDataStatement

class CreateDataStatement(*table*, *index*, *columns=None*)

Bases: `sasoptpy.abstract.statement.statement_base.Statement`

__init__(*self*, *table*, *index*, *columns=None*)

Initialize self. See help(type(self)) for accurate signature.

Methods

`__init__`(self, table, index[, columns])	Initialize self.
`append`(self, element, **kwargs)	
`create_data`(*args, **kwargs)	
`get_column_str`(c)	
`get_columns_expr`(self)	
`get_index_expr`(self)	
`get_response`(self)	
`get_table_expr`(self)	
`get_table_name`(self)	
`is_internal`(self)	
`set_internal`(self, value)	
`set_response`(self, response)	

sasoptpy.abstract.statement.DropStatement

class DropStatement(***kwargs*)

Bases: `sasoptpy.abstract.statement.statement_base.Statement`

__init__(**args*, ***kwargs*)

Methods

`__init__`(*args, **kwargs)
`append`(self, element)
`drop_constraint`(*constraints)
`get_response`(self)
`is_internal`(self)
`model_drop_constraint`(_, c)
`set_internal`(self, value)
`set_response`(self, response)

sasoptpy.abstract.statement.ForLoopStatement

class ForLoopStatement(**args*)

Bases: `sasoptpy.abstract.statement.statement_base.Statement`

__init__(*self*, **args*)

Initialize self. See help(type(self)) for accurate signature.

Methods

`__init__`(self, *args)	Initialize self.
`append`(self, element)	
`for_loop`(*args)	
`get_response`(self)	
`is_internal`(self)	
`set_internal`(self, value)	
`set_response`(self, response)	

sasoptpy.abstract.statement.IfElseStatement

class IfElseStatement(*logic_expression*, *if_statement*, *else_statement=None*)

Bases: `sasoptpy.abstract.statement.if_else.NestedConditions`

__init__(*self*, *logic_expression*, *if_statement*, *else_statement=None*)

Initialize self. See help(type(self)) for accurate signature.

Methods

`__init__`(self, logic_expression, if_statement)	Initialize self.
`append`(self, element)	
`get_response`(self)	
`if_condition`(logic_expression, if_statement)	
`is_internal`(self)	
`set_internal`(self, value)	
`set_response`(self, response)	

sasoptpy.abstract.statement.LiteralStatement

class LiteralStatement(***kwargs*)

Bases: `sasoptpy.abstract.statement.statement_base.Statement`

__init__(**args*, ***kwargs*)

Methods

`__init__`(*args, **kwargs)	
`append`(self, literal)	
`diff`(*args)	
`expand`()	
`get_response`(self)	
`is_internal`(self)	
`set_internal`(self, value)	
`set_response`(self, response)	
`substring`(main_string, first_pos, last_pos)	
`union`(*args)	
`use_problem`(problem)	

sasoptpy.abstract.statement.ObjectiveStatement

class ObjectiveStatement(*expression*, ***kwargs*)

Bases: `sasoptpy.abstract.statement.statement_base.Statement`

__init__(*self*, *expression*, ***kwargs*)

Initialize self. See help(type(self)) for accurate signature.

Methods

`__init__`(self, expression, **kwargs)	Initialize self.
`append`(self)	
`get_response`(self)	
`is_internal`(self)	
`set_internal`(self, value)	
`set_objective`(expression, name, sense)	
`set_response`(self, response)	

sasoptpy.abstract.statement.ReadDataStatement

class ReadDataStatement(*table*, *index*, *columns=None*)

Bases: `sasoptpy.abstract.statement.statement_base.Statement`

__init__(*self*, *table*, *index*, *columns=None*)

Initialize self. See help(type(self)) for accurate signature.

Methods

`__init__`(self, table, index[, columns])	Initialize self.
`append`(self, element, **kwargs)	
`flatten_column`(col)	
`get_column_str`(c)	
`get_columns_expr`(self)	
`get_index_expr`(self)	
`get_response`(self)	
`get_table_expr`(self)	
`get_target_expr`(target)	
`is_internal`(self)	
`read_data`(*args, **kwargs)	
`set_internal`(self, value)	
`set_response`(self, response)	

sasoptpy.abstract.statement.SolveStatement

class SolveStatement(**args, **kwargs*)

Bases: `sasoptpy.abstract.statement.statement_base.Statement`

`__init__`(*self, *args, **kwargs*)

Initialize self. See help(type(self)) for accurate signature.

Methods

`__init__`(self, *args, **kwargs)	Initialize self.
`append`(self, element)	
`get_problem_summary`(self)	
`get_response`(self)	
`get_solution_summary`(self)	
`is_internal`(self)	
`set_internal`(self, value)	
`set_response`(self, problem_summary, …)	
`solve`(*args, **kwargs)	
`solve_model`(model, **kwargs)	

sasoptpy.abstract.statement.FixStatement

class FixStatement(**elements*)

Bases: `sasoptpy.abstract.statement.statement_base.Statement`

`__init__`(*self, *elements*)

Initialize self. See help(type(self)) for accurate signature.

Methods

`__init__`(self, *elements)	Initialize self.
`append`(self, element)	
`fix`(*items)	
`get_response`(self)	
`is_internal`(self)	
`set_internal`(self, value)	
`set_response`(self, response)	

sasoptpy.abstract.statement.UnfixStatement

class UnfixStatement(**elements*)

Bases: `sasoptpy.abstract.statement.statement_base.Statement`

__init__(*self, *elements*)

Initialize self. See help(type(self)) for accurate signature.

Methods

`__init__`(self, *elements)	Initialize self.
`append`(self, element)	
`get_response`(self)	
`is_internal`(self)	
`set_internal`(self, value)	
`set_response`(self, response)	
`unfix`(*items)	

sasoptpy.abstract.statement.PrintStatement

class PrintStatement(**args*)

Bases: `sasoptpy.abstract.statement.statement_base.Statement`

__init__(*self, *args*)

Initialize self. See help(type(self)) for accurate signature.

Methods

`__init__`(self, *args)	Initialize self.
`allow_print_names`(self)	
`append`(self, arg)	
`get_response`(self)	
`is_internal`(self)	
`print_item`(*args)	
`put_item`(*args[, names])	
`set_internal`(self, value)	
`set_print_type`(self, print_type)

5.3 Interface

5.3.1 Interface

CAS (Viya)

CASMediator(caller, cas_session)	Handles the connection between sasoptpy and SAS Viya (CAS) server

sasoptpy.interface.CASMediator

class CASMediator(*caller*, *cas_session*)

Bases: `sasoptpy.interface.solver.mediator.Mediator`

Handles the connection between sasoptpy and SAS Viya (CAS) server

Parameters

caller [`Model` or `Workspace`] Model or workspace that mediator belongs to

cas_session [`swat.cas.connection.CAS`] CAS connection

Notes

- CAS Mediator is used by `Model` and `Workspace` objects internally.

Model

CASMediator.solve(self, **kwargs)	Solve action for `Model` objects
CASMediator.tune(self, **kwargs)	Checks if CAS session has optimizaiton.tuner capability and calls `tune_problem()`
CASMediator.tune_problem(self, **kwargs)	Calls optimization.tuner CAS action to find out ideal configuration
CASMediator.solve_with_mps(self, **kwargs)	Submits the problem in MPS (DataFrame) format, supported by old versions
CASMediator.solve_with_optmodel(self, **kwargs)	Submits the problem in OPTMODEL format
CASMediator.parse_cas_solution(self)	Performs post-solve operations
CASMediator.parse_cas_table(self, table)	Converts requested `swat.cas.table.CASTable` objects to `swat.dataframe.SASDataFrame`
CASMediator.set_variable_values(self, solution)	Performs post-solve assignment of variable values
CASMediator.set_constraint_values(self, solution)	Performs post-solve assignment of constraint values
CASMediator.set_model_objective_value(self)	Performs post-solve assignment of objective values

Continued on next page

Table 42 – continued from previous page

CASMediator.set_variable_init_values(self)	Performs post-solve assignment of variable initial values
CASMediator.upload_user_blocks(self)	Uploads user-defined decomposition blocks to the CAS server
CASMediator.upload_model(self[, name, ...])	Converts internal model to MPS table and upload to CAS session

sasoptpy.interface.CASMediator.solve

CASMediator.**solve**(*self*, ***kwargs*)
Solve action for Model objects

sasoptpy.interface.CASMediator.tune

CASMediator.**tune**(*self*, ***kwargs*)
Checks if CAS session has optimizaiton.tuner capability and calls tune_problem()

sasoptpy.interface.CASMediator.tune_problem

CASMediator.**tune_problem**(*self*, ***kwargs*)
Calls optimization.tuner CAS action to find out ideal configuration

sasoptpy.interface.CASMediator.solve_with_mps

CASMediator.**solve_with_mps**(*self*, ***kwargs*)
Submits the problem in MPS (DataFrame) format, supported by old versions

Parameters

kwargs [dict] Keyword arguments for solver settings and options

Returns

primal_solution [swat.dataframe.SASDataFrame] Solution of the model or None

sasoptpy.interface.CASMediator.solve_with_optmodel

CASMediator.**solve_with_optmodel**(*self*, ***kwargs*)
Submits the problem in OPTMODEL format

Parameters

kwargs [dict] Keyword arguments for solver settings and options

Returns

primal_solution [swat.dataframe.SASDataFrame] Solution of the model or None

sasoptpy.interface.CASMediator.parse_cas_solution

`CASMediator.parse_cas_solution(self)`

Performs post-solve operations

Returns

solution [`swat.dataframe.SASDataFrame`] Solution of the problem

sasoptpy.interface.CASMediator.parse_cas_table

`CASMediator.parse_cas_table(self, table)`

Converts requested `swat.cas.table.CASTable` objects to `swat.dataframe.SASDataFrame`

sasoptpy.interface.CASMediator.set_variable_values

`CASMediator.set_variable_values(self, solution)`

Performs post-solve assignment of variable values

Parameters

solution [class:*swat.dataframe.SASDataFrame*] Primal solution of the problem

sasoptpy.interface.CASMediator.set_constraint_values

`CASMediator.set_constraint_values(self, solution)`

Performs post-solve assignment of constraint values

Parameters

solution [class:*swat.dataframe.SASDataFrame*] Primal solution of the problem

sasoptpy.interface.CASMediator.set_model_objective_value

`CASMediator.set_model_objective_value(self)`

Performs post-solve assignment of objective values

Parameters

solution [class:*swat.dataframe.SASDataFrame*] Primal solution of the problem

sasoptpy.interface.CASMediator.set_variable_init_values

`CASMediator.set_variable_init_values(self)`

Performs post-solve assignment of variable initial values

Parameters

solution [class:*swat.dataframe.SASDataFrame*] Primal solution of the problem

sasoptpy.interface.CASMediator.upload_user_blocks

CASMediator.**upload_user_blocks**(*self*)

Uploads user-defined decomposition blocks to the CAS server

Returns

name [string] CAS table name of the user-defined decomposition blocks

Examples

```
>>> userblocks = m.upload_user_blocks()
>>> m.solve(milp={'decomp': {'blocks': userblocks}})
```

sasoptpy.interface.CASMediator.upload_model

CASMediator.**upload_model**(*self*, *name=None*, *replace=True*, *constant=False*, *verbose=False*)

Converts internal model to MPS table and upload to CAS session

Parameters

name [string, optional] Desired name of the MPS table on the server

replace [boolean, optional] Option to replace the existing MPS table

Returns

frame [`swat.cas.table.CASTable`] Reference to the uploaded CAS Table

Notes

- This method returns None if the model session is not valid.
- Name of the table is randomly assigned if name argument is None or not given.
- This method should not be used if `Model.solve()` is going to be used. `Model.solve()` calls this method internally.

Workspace

CASMediator.submit(self, **kwargs)	Submit action for custom input and `Workspace` objects
CASMediator.submit_optmodel_code(self, ...)	Converts caller into OPTMODEL code and submits using optimization.runOptmodel action
CASMediator.parse_cas_workspace_response(self)	Parses results of workspace submission
CASMediator.set_workspace_variable_values(...)	Performs post-solve assignment of `Workspace` variable values

sasoptpy.interface.CASMediator.submit

CASMediator.**submit**(*self*, ***kwargs*)
Submit action for custom input and `Workspace` objects

sasoptpy.interface.CASMediator.submit_optmodel_code

CASMediator.**submit_optmodel_code**(*self*, ***kwargs*)
Converts caller into OPTMODEL code and submits using optimization.runOptmodel action

Parameters

kwargs : Solver settings and options

sasoptpy.interface.CASMediator.parse_cas_workspace_response

CASMediator.**parse_cas_workspace_response**(*self*)
Parses results of workspace submission

sasoptpy.interface.CASMediator.set_workspace_variable_values

CASMediator.**set_workspace_variable_values**(*self*, *solution*)
Performs post-solve assignment of `Workspace` variable values

SAS

SASMediator(caller, sas_session)	Handles the connection between sasoptpy and SAS instance

sasoptpy.interface.SASMediator

class SASMediator(*caller*, *sas_session*)
Bases: `sasoptpy.interface.solver.mediator.Mediator`

Handles the connection between sasoptpy and SAS instance

Parameters

caller [`Model` or `Workspace`] Model or workspace that mediator belongs to

sas_session [`saspy.SASsession`] SAS session object

Notes

- SAS Mediator is used by `Model` and `Workspace` objects internally.

Model

SASMediator.solve(self, **kwargs)	Solve action for `Model` objects
SASMediator.solve_with_mps(self, **kwargs)	Submits the problem in MPS (DataFrame) format, supported by old versions
SASMediator.solve_with_optmodel(self, **kwargs)	Submits the problem in OPTMODEL format
SASMediator.parse_sas_mps_solution(self)	Parses MPS solution after *solve* and returns solution
SASMediator.parse_sas_solution(self)	Performs post-solve operations
SASMediator.parse_sas_table(self, table_name)	Converts requested table name into `pandas.DataFrame`
SASMediator.convert_to_original(self, table)	Converts variable names to their original format if a placeholder gets used
SASMediator.perform_postsolve_operations(self)	Performs post-solve operations for proper output display

sasoptpy.interface.SASMediator.solve

`SASMediator.`**`solve`**`(`*self*, ***kwargs*`)`

Solve action for `Model` objects

sasoptpy.interface.SASMediator.solve_with_mps

`SASMediator.`**`solve_with_mps`**`(`*self*, ***kwargs*`)`

Submits the problem in MPS (DataFrame) format, supported by old versions

Parameters

kwargs [dict] Keyword arguments for solver settings and options

Returns

primal_solution [`pandas.DataFrame`] Solution of the model or None

sasoptpy.interface.SASMediator.solve_with_optmodel

`SASMediator.`**`solve_with_optmodel`**`(`*self*, ***kwargs*`)`

Submits the problem in OPTMODEL format

Parameters

kwargs [dict] Keyword arguments for solver settings and options

Returns

primal_solution [`pandas.DataFrame`] Solution of the model or None

sasoptpy.interface.SASMediator.parse_sas_mps_solution

`SASMediator.parse_sas_mps_solution(self)`
Parses MPS solution after *solve* and returns solution

sasoptpy.interface.SASMediator.parse_sas_solution

`SASMediator.parse_sas_solution(self)`
Performs post-solve operations

Returns

solution [`pandas.DataFrame`] Solution of the problem

sasoptpy.interface.SASMediator.parse_sas_table

`SASMediator.parse_sas_table(self, table_name)`
Converts requested table name into `pandas.DataFrame`

sasoptpy.interface.SASMediator.convert_to_original

`SASMediator.convert_to_original(self, table)`
Converts variable names to their original format if a placeholder gets used

sasoptpy.interface.SASMediator.perform_postsolve_operations

`SASMediator.perform_postsolve_operations(self)`
Performs post-solve operations for proper output display

Workspace

`SASMediator.submit`(self, **kwargs)	Submit action for custom input and `Workspace` objects
`SASMediator.submit_optmodel_code`(self, ...)	Submits given `Workspace` object in OPTMODEL format
`SASMediator.parse_sas_workspace_response`(self)	Parses results of workspace submission
`SASMediator.set_workspace_variable_values`(...)	Performs post-solve assignment of `Workspace` variable values

sasoptpy.interface.SASMediator.submit

SASMediator.**submit**(*self*, ***kwargs*)
Submit action for custom input and `Workspace` objects

sasoptpy.interface.SASMediator.submit_optmodel_code

SASMediator.**submit_optmodel_code**(*self*, ***kwargs*)
Submits given `Workspace` object in OPTMODEL format

Parameters

kwargs : Solver settings and options

sasoptpy.interface.SASMediator.parse_sas_workspace_response

SASMediator.**parse_sas_workspace_response**(*self*)
Parses results of workspace submission

sasoptpy.interface.SASMediator.set_workspace_variable_values

SASMediator.**set_workspace_variable_values**(*self*, *solution*)
Performs post-solve assignment of `Workspace` variable values

5.4 Functions

5.4.1 Functions

Utility Functions

dict_to_frame(dictobj[, cols])	Converts dictionaries to DataFrame objects for pretty printing
exp_range(start, stop[, step])	Creates a set within given range
flatten_frame(df[, swap])	Converts a `pandas.DataFrame` object into `pandas.Series`
get_solution_table(*argv[, key, rhs])	
quick_sum(argv)	
reset()	Resets package configs and internal counters

sasoptpy.dict_to_frame

dict_to_frame (*dictobj*, *cols=None*)

Converts dictionaries to DataFrame objects for pretty printing

Parameters

dictobj [dict] Dictionary to be converted

cols [list, optional] Column names

Returns

frobj [DataFrame] DataFrame representation of the dictionary

Examples

```
>>> d = {'coal': {'period1': 1, 'period2': 5, 'period3': 7},
>>>      'steel': {'period1': 8, 'period2': 4, 'period3': 3},
>>>      'copper': {'period1': 5, 'period2': 7, 'period3': 9}}
>>> df = so.dict_to_frame(d)
>>> print(df)
        period1  period2  period3
coal          1        5        7
copper        5        7        9
steel         8        4        3
```

sasoptpy.exp_range

exp_range (*start*, *stop*, *step=1*)

Creates a set within given range

Parameters

start [Expression] First value of the range

stop [Expression] Last value of the range

step [Expression, optional] Step size of the range

Returns

exset [Set] Set that represents the range

Examples

```
>>> N = so.Parameter(name='N')
>>> p = so.exp_range(1, N)
>>> print(p._defn())
set 1..N;
```

sasoptpy.flatten_frame

flatten_frame(*df*, *swap=False*)

Converts a pandas.DataFrame object into pandas.Series

Parameters

df [pandas.DataFrame] DataFrame to be flattened

swap [boolean, optional] Option to use columns as first index

Returns

new_frame [pandas.DataFrame] A new DataFrame where indices consist of index and columns names as tuples

Examples

```
>>> price = pd.DataFrame([
>>>     [1, 5, 7],
>>>     [8, 4, 3],
>>>     [5, 7, 9]], columns=['period1', 'period2', 'period3']).\
>>>     set_index([['coal', 'steel', 'copper']])
>>> print('Price data: \n{}'.format(price))
>>> price_f = so.flatten_frame(price)
>>> print('Price data: \n{}'.format(price_f))
Price data:
        period1  period2  period3
coal          1        5        7
steel         8        4        3
copper        5        7        9
Price data:
(coal, period1)      1
(coal, period2)      5
(coal, period3)      7
(steel, period1)     8
(steel, period2)     4
(steel, period3)     3
(copper, period1)    5
(copper, period2)    7
(copper, period3)    9
dtype: int64
```

sasoptpy.get_solution_table

get_solution_table(**argv*, *key=None*, *rhs=False*)

sasoptpy.quick_sum

quick_sum(*argv*)

sasoptpy.reset

reset()

Resets package configs and internal counters

Abstract Actions

actions.read_data(table, index, columns)	Reads data tables inside Set and Parameter objects
actions.create_data(table, index, columns)	Creates data tables from variables, parameters and expressions
actions.solve([options, primalin])	Solves the active optimization problem and generates results
actions.for_loop(*args)	Creates a for-loop container that is to be executed on server-side
actions.cofor_loop(*args)	Creates a cofor-loop that is to be executed on server-side concurrently
actions.if_condition(logic_expression, ...)	Creates an if-else block
actions.switch_conditions(**args)	Creates several if-else blocks using given arguments
actions.set_value(left, right)	Creates an assignment statement
actions.fix(*args)	Fixes values of variables to given values
actions.unfix(*args)	Unfixes values of variables
actions.set_objective(expression, name, sense)	Sets objective function
actions.print_item(*args)	Prints given argument list on server-side
actions.put_item(*args[, names])	Prints given item values to output log
actions.expand()	Prints expanded problem to output
actions.drop(*args)	Drops given constraints or constraint groups from model
actions.restore(*args)	Restores dropped constraint and constraint groups
actions.union(*args)	Aggregates given sets and set expressions
actions.diff(left, right)	Gets the difference between set and set expressions
actions.substring(main_string, first_pos, ...)	Gets the substring of given positions
actions.use_problem(problem)	Changes the currently active problem

sasoptpy.actions.read_data

read_data(*table*, *index*, *columns*)

Reads data tables inside Set and Parameter objects

Parameters

table [string or `swat.cas.table.CASTable`] Table object or name to be read, case insensitive

index [dict] Index properties of the table

Has two main members:

- **target** [`sasoptpy.abstract.Set`] Target Set object to be read into
- **key** [string, list or None] Column name that will be read from.

  For multiple indices it should be a list of string or `sasoptpy.abstract.SetIterator` objects

For a given Set *YEAR* and column name *year_no*, the index dictionary should be written as:

```
>>> {'target': YEAR, 'key': 'year_no'}
```

If index is simply the row number, use *'key': so.N* which is equivalent to special *_N_* character at SAS language.

columns [list] A list of dictionaries, each holding column properties.

Columns are printed in given order. Each column should be represented as a dictionary with following fields:

- **target** [`sasoptpy.abstract.ParameterGroup`] Target parameter object to be read into
- **column** [string] Column name to be read from
- **index** [`sasoptpy.SetIterator`, optional] Sub-index for specific column, needed for complex operations

If the name of the `sasoptpy.abstract.Parameter` object is same as the column name, calling

```
>>> p = so.Parameter(name='price')
>>> read_data(..., columns=[{'target': p}])
```

is enough. For reading a different column name, *column* field should be given:

```
>>> {'target': p, 'column': 'price_usd'}
```

When working with Parameter Group objects, sometimes a secondary loop is needed. This is achieved by using *index* field, along with `sasoptpy.abstract.statement.ReadDataStatement.append()` method.

Returns

r [`sasoptpy.abstract.statement.ReadDataStatement`] Read data statement object, that includes all properties

Additional columns can be added using `sasoptpy.abstract.statement.ReadDataStatement.append()` function.

See also:

`tests.abstract.statement.test_read_data.TestReadData`

Examples

Reading a regular set

```
>>> with Workspace('test_workspace') as ws:
>>>     ITEMS = Set(name='ITEMS')
>>>     value = ParameterGroup(ITEMS, name='value', init=0)
>>>     get = VariableGroup(ITEMS, name='get', vartype=so.INT, lb=0)
>>>     read_data(
...         table="values",
...         index={'target': ITEMS, 'key': None},
...         columns=[{'target': value}])
>>> print(so.to_optmodel(w))
proc optmodel;
    set ITEMS;
    num value {ITEMS} init 0;
    var get {{ITEMS}} integer >= 0;
    read data values into ITEMS value;
quit;
```

Reading with row index

```
>>> with so.Workspace('test_read_data_n') as ws:
>>>     ASSETS = so.Set(name='ASSETS')
>>>     ret = so.ParameterGroup(ASSETS, name='return', ptype=so.NUM)
>>>     read_data(
...         table='means',
...         index={'target': ASSETS, 'key': so.N},
...         columns=[{'target': ret}]
...     )
>>> print(so.to_optmodel(w))
proc optmodel;
    set ASSETS;
    num return {ASSETS};
    read data means into ASSETS=[_N_] return;
quit;
```

Reading with no index set and subindex

```
>>> with so.Workspace('test_read_data_no_index_expression') as ws:
>>>     ASSETS = so.Set(name='ASSETS')
>>>     cov = so.ParameterGroup(ASSETS, ASSETS, name='cov', init=0)
>>>     with iterate(ASSETS, 'asset1') as asset1, iterate(ASSETS, 'asset2') as␣
↪asset2:
>>>         read_data(
...             table='covdata',
...             index={'key': [asset1, asset2]},
...             columns=[
...                 {'target': cov},
...                 {'target': cov[asset2, asset1],
...                 'column': 'cov'}])
>>> print(so.to_optmodel(w))
proc optmodel;
    set ASSETS;
    num cov {ASSETS, ASSETS} init 0;
    read data covdata into [asset1 asset2] cov cov[asset2, asset1]=cov;
quit;
```

Reading a column with multiple indices

```
>>> with so.Workspace(name='test_read_data_idx_col') as ws:
>>>     dow = so.Set(name='DOW', value=so.exp_range(1, 6))
>>>     locs = so.Set(name='LOCS', settype=so.STR)
>>>     demand = so.ParameterGroup(locs, dow, name='demand')
>>>     with iterate(locs, name='loc') as loc:
>>>         r = read_data(
...             table='dmnd',
...             index={'target': locs, 'key': loc}
...         )
>>>         with iterate(dow, name='d') as d:
>>>             r.append({
...                 'index': d,
...                 'target': demand[loc, d],
...                 'column': concat('day', d)
...             })
>>> optmodel_code = so.to_optmodel(ws)
proc optmodel;
    set DOW = 1..5;
    set <str> LOCS;
    num demand {LOCS, DOW};
    read data dmnd into LOCS=[loc] {d in DOW} < demand[loc, d]=col('day' || d) >;
quit;
```

sasoptpy.actions.create_data

create_data (*table*, *index*, *columns*)

Creates data tables from variables, parameters and expressions

Parameters

table [string] Name of the table to be created

index [dict] Table index properties

This dictionary can be empty if no index is needed. It can have following fields:

- **key** [list] List of index keys. Keys can be string or *sasoptpy.abstract.SetIterator* objects
- **set** [list] List of sets, that is being assigned to keys

columns [list] List of columns. Columns can be *sasoptpy.abstract.Parameter*, *sasoptpy.abstract.ParameterGroup* objects or dictionaries. If given as a dictionary, each can have following keys:

- **name** [string] Name of the column in output table
- **expression** [`sasoptpy.core.Expression`] Any expression
- **index** [list or *sasoptpy.abstract.SetIterator*] Index for internal loops

The *index* field can be used when a subindex is needed. When given as a list, members should be *sasoptpy.abstract.SetIterator* objects. See examples for more details.

tests.abstract.statement.test_create_data.TestCreateData

Examples

Regular column

```
>>> with so.Workspace('w') as w:
>>>     m = so.Parameter(name='m', value=7)
>>>     n = so.Parameter(name='n', value=5)
>>>     create_data(table='example', index={}, columns=[m, n])
>>> print(so.to_optmodel(w))
proc optmodel;
    num m = 7;
    num n = 5;
    create data example from m n;
quit;
```

Column with name

```
>>> with so.Workspace('w') as w:
>>>     m = so.Parameter(name='m', value=7)
>>>     n = so.Parameter(name='n', value=5)
>>>     create_data(table='example', index={}, columns=[
...         {'name': 'ratio', 'expression': m/n}
...     ])
>>> print(so.to_optmodel(w))
proc optmodel;
    num m = 7;
    num n = 5;
    create data example from ratio=((m) / (n));
quit;
```

Column name with concat

```
>>> from sasoptpy.util import concat
>>> with so.Workspace('w') as w:
>>>     m = so.Parameter(name='m', value=7)
>>>     n = so.Parameter(name='n', value=5)
>>>     create_data(table='example', index={}, columns=[
...         {'name': concat('s', n), 'expression': m+n}
...     ])
>>> print(so.to_optmodel(w))
proc optmodel;
    num m = 7;
    num n = 5;
    create data example from col('s' || n)=(m + n);
quit;
```

Table with index

```
>>> with so.Workspace('w') as w:
>>>     m = so.ParameterGroup(
>>>         so.exp_range(1, 6), so.exp_range(1, 4), name='m', init=0)
>>>     m[1, 1] = 1
>>>     m[4, 1] = 1
>>>     S = so.Set(name='ISET', value=[i**2 for i in range(1, 3)])
>>>     create_data(
...         table='example',
...         index={'key': ['i', 'j'], 'set': [S, [1, 2]]},
...         columns=[m]
```

(continues on next page)

(continued from previous page)

```
...     )
>>> print(so.to_optmodel(w))
proc optmodel;
    num m {1..5, 1..3} init 0;
    m[1, 1] = 1;
    m[4, 1] = 1;
    set ISET = {1,4};
    create data example from [i j] = {{ISET,{1,2}}} m;
quit;
```

Index over Python range

```
>>> with so.Workspace('w') as w:
>>>     s = so.Set(name='S', value=so.exp_range(1, 6))
>>>     x = so.VariableGroup(s, name='x')
>>>     x[1] = 1
>>>     create_data(table='example',
...         index={'key': ['i'], 'set': so.exp_range(1, 4)}, columns=[x])
>>> print(so.to_optmodel(w))
proc optmodel;
    set S = 1..5;
    var x {{S}};
    x[1] = 1;
    create data example from [i] = {1..3} x;
quit;
```

Append column with index

```
>>> from sasoptpy.util import iterate, concat
>>> with so.Workspace('w', session=session) as w:
>>>     alph = so.Set(name='alph', settype=so.string, value=['a', 'b', 'c'])
>>>     x = so.VariableGroup([1, 2, 3], alph, name='x', init=2)
>>>     with iterate(so.exp_range(1, 4), name='i') as i:
>>>         c = create_data(
...             table='example',
...             index={'key': [i], 'set': [i.get_set()]})
>>>         with iterate(alph, name='j') as j:
>>>             c.append(
...                 {'name': concat('x', j),
...                  'expression': x[i, j],
...                  'index': j})
>>> print(so.to_optmodel(w))
proc optmodel;
    set <str> alph = {'a','b','c'};
    var x {{1,2,3}, {alph}} init 2;
    create data example from [i] = {{1..3}} {j in alph} < col('x' || j)=(x[i, j])␣
↪>;
quit;
```

Multiple column indices

```
>>> from sasoptpy.util import concat, iterate
>>> with so.Workspace('w') as w:
>>>     S = so.Set(name='S', value=[1, 2, 3])
>>>     T = so.Set(name='T', value=[1, 3, 5])
>>>     x = so.VariableGroup(S, T, name='x', init=1)
>>>     with iterate(S, name='i') as i, iterate(T, name='j') as j:
```

(continues on next page)

(continued from previous page)

```
>>>         create_data(
...             table='out',
...             index={},
...             columns=[
...                 {'name': concat('x', concat(i, j)), 'expression': x[i, j],
...                  'index': [i, j]}])
>>> print(so.to_optmodel(w))
proc optmodel;
    set S = {1,2,3};
    set T = {1,3,5};
    var x {{S}, {T}} init 1;
    create data out from {i in S, j in T} < col('x' || i || j)=(x[i, j]) >;
quit;
```

sasoptpy.actions.solve

solve (*options=None*, *primalin=False*)

Solves the active optimization problem and generates results

Parameters

options [dict, optional] Solver options

This dictionary can have several fields.

- **with** [string] Name of the solver, see possible values under Notes.

See *Solver Options* for a list of solver options. All fields in options (except *with*) is passed directly to the solver.

primalin [bool, optional] Switch for using existing variable values as an initial point in MILP solver

Returns

ss [`sasoptpy.abstract.statement.SolveStatement`] Solve statement object.

Contents of the response can be grabbed using *get_response* function.

Notes

Possible solver names for *with* parameter:

- *lp* : Linear programming
- *milp* : Mixed integer linear programming
- *nlp* : General nonlinear programming
- *qp* : Quadratic programming
- *blackbox* : Black-box optimization

SAS Optimization also has Constraint Programming (clp) and Network Solver (network) but they are not currently supported.

Examples

Regular solve

```
>>> with so.Workspace('w') as w:
>>>     x = so.Variable(name='x', lb=1, ub=10)
>>>     o = so.Objective(2*x, sense=so.maximize, name='obj')
>>>     s = solve()
>>>     p = print_item(x)
>>> print(so.to_optmodel(w))
proc optmodel;
    var x >= 1 <= 10;
    max obj = 2 * x;
    solve;
    print x;
quit;
```

Option alternatives

```
>>> with so.Workspace('w') as w:
>>>     # Problem declaration, etc..
>>>     solve()
>>>     solve(options={'with': 'milp'})
>>>     solve(options={'with': 'milp'}, primalin=True)
>>>     solve(options={'with': 'milp', 'presolver': None, 'feastol': 1e-6,
>>>                    'logfreq': 2, 'maxsols': 3, 'scale': 'automatic',
>>>                    'restarts': None, 'cutmir': 'aggressive'})
>>> print(so.to_optmodel(w))
proc optmodel;
    solve;
    solve with milp;
    solve with milp / primalin;
    solve with milp / presolver=None feastol=1e-06 logfreq=2 maxsols=3␣
↪scale=automatic restarts=None cutmir=aggressive;
quit;
```

sasoptpy.actions.for_loop

for_loop (**args*)

Creates a for-loop container that is to be executed on server-side

Parameters

args [*sasoptpy.abstract.Set* objects] Any number of Set objects can be given

Returns

set_iterator [*sasoptpy.abstract.SetIterator*, *sasoptpy.abstract.SetIteratorGroup*] Set iterators to be used inside for-loop

See also:

sasoptpy.actions.cofor_loop()

Notes

For tasks that can be run concurrently, consider using *sasoptpy.actions.cofor_loop()*

Examples

Regular for loop

```
>>> with so.Workspace('w') as w:
>>>     r = so.exp_range(1, 11)
>>>     x = so.VariableGroup(r, name='x')
>>>     for i in for_loop(r):
>>>         x[i] = 1
>>> print(so.to_optmodel(w))
proc optmodel;
    var x {{1,2,3,4,5,6,7,8,9,10}};
    for {o13 in 1..10} do;
        x[o13] = 1;
    end;
quit;
```

Nested for loops

```
>>> from sasoptpy.actions import put_item
>>> with so.Workspace('w') as w:
>>>     for i in for_loop(range(1, 3)):
>>>         for j in for_loop(['a', 'b']):
>>>             put_item(i, j)
>>> print(so.to_optmodel(w))
proc optmodel;
    for {o2 in 1..2} do;
        for {o5 in {'a','b'}} do;
            put o2 o5;
        end;
    end;
quit;
```

Multiple set for-loops

```
>>> with so.Workspace('w') as w:
>>>     r = so.Set(name='R', value=range(1, 11))
>>>     c = so.Set(name='C', value=range(1, 6))
>>>     a = so.ParameterGroup(r, c, name='A', ptype=so.number)
>>>     for (i, j) in for_loop(r, c):
>>>         a[i, j] = 1
>>> print(so.to_optmodel(w))
proc optmodel;
    set R = 1..10;
    set C = 1..5;
    num A {R, C};
    for {o5 in R, o7 in C} do;
        A[o5, o7] = 1;
    end;
quit;
```

sasoptpy.actions.cofor_loop

cofor_loop(**args*)

Creates a cofor-loop that is to be executed on server-side concurrently

Parameters

args [sasoptpy.abstract.Set objects] Any number of Set objects can be given

Returns

set_iterator [sasoptpy.abstract.SetIterator, sasoptpy.abstract.SetIteratorGroup] Set iterators to be used inside cofor-loop

See also:

sasoptpy.actions.for_loop()

Notes

A cofor-loop runs its content concurrently. For tasks that depend on each other, consider using sasoptpy.actions.for_loop()

Examples

```
>>> with so.Workspace('w') as w:
>>>     x = so.VariableGroup(6, name='x', lb=0)
>>>     so.Objective(
>>>         so.expr_sum(x[i] for i in range(6)), name='z', sense=so.MIN)
>>>     a1 = so.Constraint(x[1] + x[2] + x[3] <= 4, name='a1')
>>>     for i in cofor_loop(so.exp_range(3, 6)):
>>>         fix(x[1], i)
>>>         solve()
>>>         put_item(i, x[1], so.Symbol('_solution_status_'), names=True)
>>> print(so.to_optmodel(w))
proc optmodel;
    var x {{0,1,2,3,4,5}} >= 0;
    min z = x[0] + x[1] + x[2] + x[3] + x[4] + x[5];
    con a1 : x[1] + x[2] + x[3] <= 4;
    cofor {o13 in 3..5} do;
        fix x[1]=o13;
        solve;
        put o13= x[1]= _solution_status_=;
    end;
quit;
```

sasoptpy.actions.if_condition

if_condition (*logic_expression*, *if_statement*, *else_statement=None*)

Creates an if-else block

Parameters

logic_expression [*sasoptpy.Constraint* or sasoptpy.abstract.Condition] Logical condition for the True case

For the condition, it is possible to combine constraints, such as

```
>>> a = so.Parameter(value=5)
>>> if_condition((a < 3) | (a > 6), func1, func2)
```

Constraints should be combined using bitwise operators (& for *and*, | for *or*).

if_statement [function or IfElseStatement] Python function or if-else statement to be called if the condition is True

else_statement [function or IfElseStatement, optional] Python function or if-else statement to be called if the condition is False

Examples

Regular condition

```
>>> with so.Workspace('w') as w:
>>>     x = so.Variable(name='x')
>>>     x.set_value(0.5)
>>>     def func1():
>>>         x.set_value(1)
>>>     def func2():
>>>         x.set_value(0)
>>>     if_condition(x > 1e-6, func1, func2)
>>> print(so.to_optmodel(w))
proc optmodel;
    var x;
    x = 0.5;
    if x > 1e-06 then do;
        x = 1;
    end;
    else do;
        x = 0;
    end;
quit;
```

Combined conditions

```
>>> with so.Workspace('w') as w:
>>>     p = so.Parameter(name='p')
>>>     def case1():
>>>         p.set_value(10)
>>>     def case2():
>>>         p.set_value(20)
>>>     r = so.Parameter(name='r', value=10)
>>>     if_condition((r < 5) | (r > 10), case1, case2)
>>> print(so.to_optmodel(w))
```

(continues on next page)

(continued from previous page)

```
proc optmodel;
    num p;
    num r = 10;
    if (r < 5) or (r > 10) then do;
        p = 10;
    end;
    else do;
        p = 20;
    end;
quit;
```

sasoptpy.actions.switch_conditions

switch_conditions(***args*)

Creates several if-else blocks using given arguments

Parameters

args : Several arguments can be passed to the function

If an argument is a Constraint or Condition (combined Constraints) the following callable argument is used as a case

Examples

```
>>> with so.Workspace('w') as w:
>>>     x = so.Variable(name='x')
>>>     p = so.Parameter(name='p')
>>>     x.set_value(2.5)
>>>     def func1():
>>>         p.set_value(1)
>>>     def func2():
>>>         p.set_value(2)
>>>     def func3():
>>>         p.set_value(3)
>>>     def func4():
>>>         p.set_value(0)
>>>     switch_conditions(x < 1, func1, x < 2, func2, x < 3, func3, func4)
>>> print(to.optmodel(w))
proc optmodel;
    var x;
    num p;
    x = 2.5;
    if x < 1 then do;
        p = 1;
    end;
    else if x < 2 then do;
        p = 2;
    end;
    else if x < 3 then do;
        p = 3;
    end;
    else do;
        p = 0;
```

(continues on next page)

(continued from previous page)

```
    end;
quit;
```

sasoptpy.actions.set_value

set_value (*left*, *right*)

Creates an assignment statement

Parameters

left [*sasoptpy.Expression*] Any expression (variable or parameter)

right [*sasoptpy.Expression* or float] Right-hand-side expression

Examples

```
>>> with so.Workspace('ex_9_1_matirx_sqrt', session=None) as w:
>>>     so.LiteralStatement('call streaminit(1);')
>>>     n = so.Parameter(name='n', value=5)
>>>     rn = so.Set(name='RN', value=so.exp_range(1, n))
>>>     A = so.ParameterGroup(rn, rn, name='A', value="10-20*rand('UNIFORM')")
>>>     P = so.ParameterGroup(rn, rn, name='P')
>>>     for i in for_loop(rn):
>>>         for j in for_loop(so.exp_range(i, n)):
>>>             set_value(P[i, j], so.expr_sum(A[i, k] * A[j, k] for k in rn))
>>> print(so.to_optmodel(w))
proc optmodel;
    call streaminit(1);
    num n = 5;
    set RN = 1..n;
    num A {RN, RN} = 10-20*rand('UNIFORM');
    num P {RN, RN};
    for {o7 in RN} do;
        for {o10 in o7..n} do;
            P[o7, o10] = sum {k in RN} (A[o7, k] * A[o10, k]);
        end;
    end;
quit;
```

sasoptpy.actions.fix

fix (**args*)

Fixes values of variables to given values

Parameters

args [*sasoptpy.Variable*, float, *sasoptpy.Expression*, tuple] Set of arguments to be fixed

Arguments get paired (if not given in tuples) to allow several fix operations

See also:

sasoptpy.actions.unfix()

tests.abstract.statement.test_fix_unfix.TestFix

Examples

Regular fix statement

```
>>> with so.Workspace('w') as w:
>>>     x = so.Variable(name='x')
>>>     fix(x, 1)
>>>     solve()
>>>     unfix(x)
>>> print(so.to_optmodel(w))
proc optmodel;
    var x;
    fix x=1;
    solve;
    unfix x;
quit;
```

Multiple fix-unfix

```
>>> with so.Workspace('w') as w:
>>>     x = so.VariableGroup(4, name='x')
>>>     for i in cofor_loop(range(4)):
>>>         fix((x[0], i), (x[1], 1))
>>>         solve()
>>>         unfix(x[0], (x[1], 2))
>>> print(so.to_optmodel(w))
proc optmodel;
    var x {{0,1,2,3}};
    cofor {o7 in 0..3} do;
        fix x[0]=o7 x[1]=1;
        solve;
        unfix x[0] x[1]=2;
    end;
quit;
```

sasoptpy.actions.unfix

unfix(**args*)

Unfixes values of variables

Parameters

args [*sasoptpy.Variable* objects] Set of arguments to be unfixed

See also:

sasoptpy.actions.fix()

tests.abstract.statement.test_fix_unfix.TestFix

Examples

Regular unfix statement

```
>>> with so.Workspace('w') as w:
>>>     x = so.Variable(name='x')
>>>     fix(x, 1)
>>>     solve()
>>>     unfix(x)
>>> print(so.to_optmodel(w))
proc optmodel;
    var x;
    fix x=1;
    solve;
    unfix x;
quit;
```

Multiple fix-unfix

```
>>> with so.Workspace('w') as w:
>>>     x = so.VariableGroup(4, name='x')
>>>     for i in cofor_loop(range(4)):
>>>         fix((x[0], i), (x[1], 1))
>>>         solve()
>>>         unfix(x[0], (x[1], 2))
>>> print(so.to_optmodel(w))
proc optmodel;
    var x {{0,1,2,3}};
    cofor {o7 in 0..3} do;
        fix x[0]=o7 x[1]=1;
        solve;
        unfix x[0] x[1]=2;
    end;
quit;
```

sasoptpy.actions.set_objective

set_objective(*expression*, *name*, *sense*)

Sets objective function

Parameters

expression [*sasoptpy.Expression*] Objective function

name [string] Name of the objective function

sense [string] Direction of the objective function, *so.MAX* or *so.MIN*

Examples

```
>>> with so.Workspace('w') as w:
>>>     x = so.Variable(name='x', lb=1)
>>>     set_objective(x ** 3, name='xcube', sense=so.minimize)
>>>     solve()
>>> print(so.to_optmodel(w))
proc optmodel;
    var x >= 1;
    MIN xcube = (x) ^ (3);
    solve;
quit;
```

sasoptpy.actions.print_item

print_item(**args*)

Prints given argument list on server-side

Parameters

args [*sasoptpy.Variable*, *sasoptpy.Expression*] Arbitrary number of arguments to be printed

These values are printed on server-side, but can be grabbed after execution

Returns

ps [*sasoptpy.abstract.statement.PrintStatement*] Print statement object.

Contents of the response can be grabbed using *get_response* function.

Examples

```
>>> with so.Workspace('w') as w:
>>>     x = so.Variable(name='x', lb=1, ub=10)
>>>     o = so.Objective(2*x, sense=so.maximize, name='obj')
>>>     s = solve()
>>>     p = print_item(x)
>>> print(so.to_optmodel(w))
proc optmodel;
    var x >= 1 <= 10;
    max obj = 2 * x;
    solve;
    print x;
quit;
>>> print(p.get_response())
      x
0  10.0
```

sasoptpy.actions.put_item

put_item(**args*, *names=None*)

Prints given item values to output log

Parameters

args [*sasoptpy.Expression*, string] Arbitrary elements to be put into log

Variables, variable groups, expressions can be printed to log

names [bool, optional] Whether name of the arguments be printed in the log

Examples

Regular operation

```
>>> with so.Workspace('w') as w:
>>>     for i in for_loop(range(1, 3)):
>>>         for j in for_loop(['a', 'b']):
>>>             put_item(i, j)
>>> print(so.to_optmodel(w))
proc optmodel;
    for {o2 in 1..2} do;
        for {o5 in {'a','b'}} do;
            put o2 o5;
        end;
    end;
quit;
```

Print with names

```
>>> with so.Workspace('w') as w:
>>>     x = so.VariableGroup(6, name='x', lb=0)
>>>     so.Objective(
>>>         so.expr_sum(x[i] for i in range(6)), name='z', sense=so.MIN)
>>>     a1 = so.Constraint(x[1] + x[2] + x[3] <= 4, name='a1')
>>>     for i in cofor_loop(so.exp_range(3, 6)):
>>>         fix(x[1], i)
>>>         solve()
>>>         put_item(i, x[1], so.Symbol('_solution_status_'), names=True)
proc optmodel;
    var x {{0,1,2,3,4,5}} >= 0;
    min z = x[0] + x[1] + x[2] + x[3] + x[4] + x[5];
    con a1 : x[1] + x[2] + x[3] <= 4;
    cofor {o13 in 3..5} do;
        fix x[1]=o13;
        solve;
        put o13= x[1]= _solution_status_=;
    end;
quit;
```

sasoptpy.actions.expand

expand()

Prints expanded problem to output

Examples

```
>>> with so.Workspace(name='w') as w:
>>>     x = so.VariableGroup(3, name='x')
>>>     self.assertEqual(x[0].sym.get_conditions_str(), '')
>>>     # solve
>>>     x[0].set_value(1)
>>>     x[1].set_value(5)
>>>     x[2].set_value(0)
>>>     c = so.ConstraintGroup(None, name='c')
>>>     with iterate([0, 1, 2], 's') as i:
>>>         with condition(x[i].sym > 0):
>>>             c[i] = x[i] >= 1
>>>     set_objective(x[0], name='obj', sense=so.MIN)
>>>     expand()
>>>     solve()
>>> print(so.to_optmodel(w))
proc optmodel;
    var x {{0,1,2}};
    x[0] = 1;
    x[1] = 5;
    x[2] = 0;
    con c {s in {0,1,2}: x[s].sol > 0} : x[s] >= 1;
    MIN obj = x[0];
    expand;
    solve;
quit;
```

sasoptpy.actions.drop

drop(**args*)

Drops given constraints or constraint groups from model

Parameters

args [*sasoptpy.Constraint*, *sasoptpy.ConstraintGroup*] Constraints to be dropped

See also:

sasoptpy.actions.restore()

Examples

```
>>> with so.Workspace('w') as w:
>>>     x = so.Variable(name='x', lb=1)
>>>     y = so.Variable(name='y', lb=0)
>>>     c = so.Constraint(sm.sqrt(x) >= 5, name='c')
>>>     o = so.Objective(x + y, sense=so.MIN, name='obj')
>>>     s = solve()
>>>     drop(c)
>>>     o2 = so.Objective(x, sense=so.MIN, name='obj2')
>>>     s2 = solve()
>>> print(so.to_optmodel(w))
proc optmodel;
    var x >= 1;
    var y >= 0;
    con c : sqrt(x) >= 5;
    min obj = x + y;
    solve;
    drop c;
    min obj2 = x;
    solve;
quit;
```

sasoptpy.actions.restore

restore(**args*)

Restores dropped constraint and constraint groups

Parameters

args [*sasoptpy.Constraint*, *sasoptpy.ConstraintGroup*] Constraints to be restored

See also:

sasoptpy.actions.drop()

Examples

```
>>> with so.Workspace('w') as w:
>>>     x = so.Variable(name='x', lb=-1)
>>>     set_objective(x**3, name='xcube', sense=so.minimize)
>>>     c = so.Constraint(x >= 1, name='xbound')
>>>     solve()
>>>     drop(c)
>>>     solve()
>>>     restore(c)
>>>     solve()
>>> print(so.to_optmodel(w))
proc optmodel;
    var x >= -1;
    MIN xcube = (x) ^ (3);
    con xbound : x >= 1;
    solve;
    drop xbound;
```

(continues on next page)

(continued from previous page)

```
    solve;
    restore xbound;
    solve;
quit;
```

sasoptpy.actions.union

union (**args*)

Aggregates given sets and set expressions

Parameters

args [*sasoptpy.abstract.Set* and sasoptpy.abstract.InlineSet] Objects to be aggregated

Examples

```
>>> from sasoptpy.actions import union, put_item
>>> with so.Workspace('w') as w:
>>>     n = so.Parameter(name='n', value=11)
>>>     S = so.Set(name='S', value=so.exp_range(1, n))
>>>     T = so.Set(name='T', value=so.exp_range(n+1, 20))
>>>     U = so.Set(name='U', value=union(S, T))
>>>     put_item(U, names=True)
>>> print(so.to_optmodel(w))
proc optmodel;
    num n = 11;
    set S = 1..n;
    set T = n+1..20;
    set U = S union T;
    put U=;
quit;
```

sasoptpy.actions.diff

diff (*left*, *right*)

Gets the difference between set and set expressions

Parameters

left [*sasoptpy.abstract.Set*] Left operand

right [*sasoptpy.abstract.Set*] Right operand

Examples

```
>>> from sasoptpy.actions import diff, put_item
>>> with so.Workspace('w') as w:
>>>     S = so.Set(name='S', value=so.exp_range(1, 20))
>>>     T = so.Set(name='T', value=so.exp_range(1, 15))
>>>     U = so.Set(name='U', value=diff(S, T))
>>>     put_item(U, names=True)
>>> print(so.to_optmodel(w))
proc optmodel;
    set S = 1..19;
    set T = 1..14;
    set U = S diff T;
    put U=;
quit;
```

sasoptpy.actions.substring

substring(*main_string*, *first_pos*, *last_pos*)
Gets the substring of given positions

Parameters

main_string [*sasoptpy.abstract.Parameter* or string] Main string

first_pos [integer] First position of the substring, starting from 1

last_pos [integer] Last position of the substring

Examples

```
>>> with so.Workspace('w') as w:
>>>     p = so.Parameter(name='p', value='random_string', ptype=so.STR)
>>>     r = so.Parameter(name='r', value=substring(p, 1, 6), ptype=so.STR)
>>>     put_item(r)
>>> print(so.to_optmodel(w))
proc optmodel;
    str p = 'random_string';
    str r = substr(p, 1, 6);
    put r;
quit;
```

sasoptpy.actions.use_problem

use_problem(*problem*)
Changes the currently active problem

Parameters

problem [*sasoptpy.Model*] Model to be activated

Examples

```
>>> from sasoptpy.actions import use_problem
>>> with so.Workspace('w') as w:
>>>     m = so.Model(name='m')
>>>     m2 = so.Model(name='m2')
>>>     use_problem(m)
>>>     x = so.Variable(name='x')
>>>     use_problem(m2)
>>>     m.solve()
>>>     m2.solve()
>>> print(so.to_optmodel(w))
proc optmodel;
    problem m;
    problem m2;
    use problem m;
    var x;
    use problem m2;
    use problem m;
    solve;
    use problem m2;
    solve;
quit;
```

Math Functions

math.math_func(exp, op, *args)	Function wrapper for math functions
math.abs(exp)	Absolute value function
math.log(exp)	Natural logarithm function
math.log2(exp)	Logarithm function to the base 2
math.log10(exp)	Logarithm function to the base 10
math.exp(exp)	Exponential function
math.sqrt(exp)	Square root function
math.mod(exp, divisor)	Modulo function
math.int(exp)	Integer value function
math.sign(exp)	Sign value function
math.max(exp, *args)	Largest value function
math.min(exp, *args)	Smallest value function
math.sin(exp)	Sine function
math.cos(exp)	Cosine function
math.tan(exp)	Tangent function

sasoptpy.math.math_func

math_func(*exp*, *op*, **args*)

Function wrapper for math functions

Parameters

exp [Expression] Expression where the math func will be applied

op [string] String representation of the math function

args [float, optional] Additional arguments

sasoptpy.math.abs

abs(*exp*)
Absolute value function

sasoptpy.math.log

log(*exp*)
Natural logarithm function

sasoptpy.math.log2

log2(*exp*)
Logarithm function to the base 2

sasoptpy.math.log10

log10(*exp*)
Logarithm function to the base 10

sasoptpy.math.exp

exp(*exp*)
Exponential function

sasoptpy.math.sqrt

sqrt(*exp*)
Square root function

sasoptpy.math.mod

mod(*exp*, *divisor*)
Modulo function

Parameters

exp [Expression] Dividend

divisor [Expression] Divisor

sasoptpy.math.int

int (*exp*)
Integer value function

sasoptpy.math.sign

sign (*exp*)
Sign value function

sasoptpy.math.max

max (*exp*, **args*)
Largest value function

sasoptpy.math.min

min (*exp*, **args*)
Smallest value function

sasoptpy.math.sin

sin (*exp*)
Sine function

sasoptpy.math.cos

cos (*exp*)
Cosine function

sasoptpy.math.tan

tan (*exp*)
Tangent function

CHAPTER

SIX

VERSION HISTORY

This page outlines changes from each release.

6.1 v0.2.1 (February 26, 2019)

6.1.1 New Features

- Support for evaluating nonlinear expressions is added, see `Expression.get_value()` and `utils._evaluate()`
- Support for multiple objectives is added for LSO solver, see `Model.set_objective()` and *Multiobjective* example
- Support for spaces inside variable indices is added
- Experimental RESTful API is added

6.1.2 Changes

- Dictionaries inside components are replaced with ordered dictionaries to preserve deterministic behavior
- Math operators are added into the keys of linear coefficient dictionaries
- Some iterators are rewritten by using the *yield* keyword for performance
- *key_name* and *col_names* parameters are added into `read_table()`

6.1.3 Bug Fixes

- Fixed: Using a single variable as an objective is producing incorrect input
- Fixed: `Expression.get_value()` fails to evaluate expressions with operators
- Fixed: `Expression.add()` overrides operators in some instances
- Fixed: Expressions with same components but different operators get summed incorrectly
- Fixed: New version of Viya complains about `pandas.DataFrame` column types
- Syntax fixes for **PEP 8** compliance

6.1.4 Notes

- A Jupyter notebook example of the Diet Problem is added
- A new example is added to show usage of experiment RESTful API
- Unit tests are added for development repository
- CD/CI integration is added for the development repository on Gitlab
- Generated models can be checked by using the hash values inside tests.responses

6.2 v0.2.0 (July 30, 2018)

6.2.1 New Features

- Support for the new *runOptmodel* CAS action is added
- Nonlinear optimization model building support is added for both SAS 9.4 and SAS Viya solvers
- Abstract model building support is added when by using SAS Viya solvers
- New object types, `Set`, `SetIterator`, `Parameter`, `ParameterValue`, `ImplicitVar`, `ExpressionDict`, and `Statement` are added for abstract model building
- `Model.to_optmodel()` method is added for exporting model objects into PROC OPTMODEL codes as a string
- Wrapper functions `read_table()` and `read_data()` are added to read CASTable and DataFrame objects into the models
- Math function wrappers are added
- `_expr` and `_defn` methods are added to all object types for producing OPTMODEL expression and definitions
- Multiple solutions are now being returned when by using *solveMilp* action and can be retrieved by using `Model.get_solution()` method
- `Model.get_variable_value()` is added to get solution values of abstract variables

6.2.2 Changes

- Variable and constraint naming schemes are replaced with OPTMODEL equivalent versions
- Variables and constraints now preserve the order they are inserted to the problem
- `Model.to_frame()` method is updated to reflect changes to VG and CG orderings
- Two solve methods, `Model.solve_on_cas()` and `Model.solve_on_viya()` are merged into `Model.solve()`
- `Model.solve()` method checks the available CAS actions and uses *runOptmodel* whenever possible
- As part of the merging process, `lp` and `milp` arguments are replaced with `options` argument in `Model.solve()` and `Model.to_optmodel()`
- An optional argument `frame` is added to `Model.solve()` for forcing to use MPS mode and *solveLp-solveMilp* actions
- Minor changes are applied to `__str__` and `__repr__` methods
- Creation indices for objects are being kept by using the return of the `register_name()` function

- Objective constant values are now being passed by using new CAS action arguments when posssible
- A linearity check is added for models
- Test folder is added to the repository

6.2.3 Bug Fixes

- Nondeterministic behavior when generating MPS files is fixed.

6.2.4 Notes

- Abstract and nonlinear models can be solved on Viya only if *runOptmodel* action is available on the CAS server.
- Three new examples are added which demonstrate abstract model building.
- Some minor changes are applied to the existing examples.

6.3 v0.1.2 (April 24, 2018)

6.3.1 New Features

- As an experimental feature, *sasoptpy* supports *saspy* connections now
- `Model.solve_local()` method is added for solving optimization problems by using SAS 9.4 installations
- `Model.drop_variable()`, `Model.drop_variables()`, `Model.drop_constraint()`, `Model.drop_constraints()` methods are added
- `Model.get_constraint()` and `Model.get_constraints()` methods are added to grab `Constraint` objects in a model
- `Model.get_variables()` method is added
- `_dual` attribute is added to the `Expression` objects
- `Variable.get_dual()` and `Constraint.get_dual()` methods are added
- `Expression.set_name()` method is added

6.3.2 Changes

- Session argument accepts `saspy.SASsession` objects
- `VariableGroup.mult()` method now supports `pandas.DataFrame`
- Type check for the `Model.set_session()` is removed to support new session types
- Problem and solution summaries are not being printed by default anymore, see `Model.get_problem_summary()` and `Model.get_solution_summary()`
- The default behavior of dropping the table after each solve is changed, but can be controlled with the `drop` argument of the `Model.solve()` method

6.3.3 Bug Fixes

- Fixed: Variables do not appear in MPS files if they are not used in the model
- Fixed: `Model.solve()` primalin argument does not pass into options

6.3.4 Notes

- A .gitignore file is added to the repository.
- A new example is added: Decentralization.
- Both *CAS/Viya* and *SAS* versions of the new example are available.
- There is a known issue with the nondeterministic behavior when creating MPS tables. This will be fixed with a hotfix after the release.
- A new option (no-ex) is added to makedocs script for skipping examples when building docs.

6.4 v0.1.1 (February 26, 2018)

6.4.1 New Features

- Initial value argument 'init' is added for `Variable` objects
- `Variable.set_init()` method is added for variables
- Initial value option 'primalin' is added to `Model.solve()` method
- Table name argument 'name', table drop option 'drop' and replace option 'replace' are added to `Model.solve()` method
- Decomposition block implementation is rewritten, block numbers does not need to be consecutive and ordered `Model.upload_user_blocks()`
- `VariableGroup.get_name()` and `ConstraintGroup.get_name()` methods are added
- `Model.test_session()` method is added for checking if session is defined for models
- `quick_sum()` function is added for faster summation of `Expression` objects

6.4.2 Changes

- methods.py is renamed to utils.py

6.4.3 Bug Fixes

- Fixed: Crash in VG and CG when a key not in the list is called
- Fixed: get_value of pandas is depreceated
- Fixed: Variables can be set as temporary expressions
- Fixed: Ordering in `get_solution_table()` is incorrect for multiple entries

6.5 v0.1.0 (December 22, 2017)

- Initial release
